GENERAL SYNOPSIS

of

BIRDS.

Vol.III.p^t. 1 ft.

LONDON:

Printed for Leigh & Sotheby, York Street, Covent Garden.

MDCCLXXXV.

PREFACE.

HE contents of the present volume, added to those of the former ones, will, it is to be hoped, make good the promise made in the first, viz. the giving "a concise account of all the Birds hitherto known;"—to attain the knowledge of which, every affistance has been given to me by my various friends, and no tristing labour bestowed by mysels.

Enough has been mentioned, in a former Preface, of the nature of this undertaking, which will occasion very little to be added in the present; a few things, however, seem necessary to be here mentioned, which are briefly the following.

The Reader will remark the occasional references made to the British Museum, as well as to that of Sir Ashton Lever:—but it must be observed, that such references could relate to those Birds only which were found there respectively at the time when each Genus was penned; and will account for several others, now seen in those repositories, not to be found in this work, which at first sight might appear to have been overlooked, though in reality occasioned merely by the additions made to each, since the particular parts were written.

Those found in the private collections of several of my friends have been referred to in their places; but, in respect to those in my own possession, it is necessary here to remark, that such are Vol. III.

meant to be pointed out to the reader by the mark + added before the trivial names in the margin.

In regard to Plates, so necessary an appendage to a work of this nature, it might perhaps have been wished that they had been executed in a more masterly stile; but I have been led to think, that where a just representation is only meant, the excellence of the artist is less necessary, and a correct outline the greatest recommendation: on this consideration I have been induced to make the attempt, by etching the plates myself, from drawings of my own, for the most part taken from the subjects themselves. How I have succeeded in this matter, I will leave to the Public to determine; all I dare say on this head is, that they are pretty accurate representations, and perhaps will not be thought an unacceptable addition to the text, especially as many of them are of subjects not to be found in any other work, being sigures of such as were discovered by our navigators to the South Seas, and those who have lately made researches towards the North Pole.

I have, for the most part, included the Birds which have lately come under inspection in one or other of the Genera of former authors; but some sew have notwithstanding arisen, which could not be reconciled to any Genus yet formed, viz. the Wattle-Bird*, Tinamou †, and Sheathbill ‡. It must likewise be here owned, that here and there a Bird will be met with interspersed in these sheets, in respect to the placing of which much difficulty has occurred; but, having one or more strong leading

* Vol. I. p. 364. † Vol. II. p. 724. ‡ Vol. III. p. 268.

characters, I have judged it more proper to place it at the heels of the Genus it seemed to have most relation to, rather than to then the memory by creating a new one.

It may not be amiss here to mention, that having still much matter remaining in manuscript, not only in addition to what has already been published, but also belonging to the present sheets, which came too late to be brought into the proper place, it will occasion me hereafter to publish such remainder by way of Appendix, as soon as a proper addition of materials, which I have now in view before me, shall have accrued, sufficient in consequence, as well as in quantity, to merit attention. This, however, will require some time; but care shall be taken that no unnecessary delay shall be made in bringing to view what surther I have to add on the subject.

Having faid thus much, nothing will remain but to conclude with my most grateful thanks for the favours of the Friends who have affisted me in my pursuits, and of the Public in general who have encouraged them—content, myself, with having made some small addition to the labours of former times, not without the hopes of being sound worth the notice of suture writers in this branch of Natural History, when the author of the present work shall be no more.

Dartford, May 2, 1785.

Vol. III.

В

and

and hooked at the end; the gape stretches beyond the eyes; the colour of it a very pale blue, except the end of the upper mandible, which is yellowish, and a red spot on the bend of it; the end of the lower blackish: irides white: the general colour of the plumage is cinereous, and soft to the touch; the belly and thighs whitish: the head large, and seems as it were covered with a black bood or cowl: the wings are very short, and of a yellowish ash-colour: the tail feathers curled, stand up on the rump, and incline to yellow, like the wings: the legs have four toes, three before and one behind; are very stout, short, and yellowish: claws black.

PLACE AND MANNERS. This is the account from Edwards, and a painting of it is now in the British Museum.

Herbert, in his Travels, feems to give an account as having feen it, though his figure is a bad one. He fays, that it "feldom weighs less than fifty pounds. The bill hooked, and bent downwards; the thrill or breathing-places in the midft; from which part to the end the colour is of a light green, mixed with pale yellow: eyes round and bright: has fine down instead of feathers: the train (like to a China-beard) is no more than three or four short feathers: the head variously dress, one half being hooded with down of a dark colour, the other half naked, and of a white hue, as if lawn were drawn over it: the legs thick and black; and the talons great." We likewise learn from him, that "the pace is slow, and the body round and fat; by some eaten as meat, but is more pleasurable to look than feed upon; and shape not a little resembling the Ostrich."

This awkward figure inhabits the islands of Mauritius (or

the Isle of France), and that of Bourbon*, in the Indian ocean.

Le Solitaire, Buf. Ois. i. p. 485 .- Leguat. Voy. i. p. 98 .- pl. in de.

SOLITARY D.

THIS is a large bird, and the male is faid to weigh sometimes forty-five pounds: it has some relation to the Turkey, as the bill and legs are like that bird's; but the bill is more bent, and it stands higher on the legs. The neck is of a proportionable length, and the eye black and lively: the head is not crested, and the general colour of the plumage is grey and brown mixed: it has scarce any tail; and the bastard wing swells out into a round knob: the wings are too short for slight, and the hind parts are rounded like a Horse's rump, being cloathed with seathers, which may be termed coverts.

DESCRIPTION.

The females are covered with sometimes brown and sometimes light yellow seathers, and appear very beautiful. This sex has also a kind of widow's peak above the bill; and the seathers on each side of the breast enlarge into two white tusts, somewhat resembling the bosom of a woman: the seathers of the thighs are rounded at the end, like shells; and, according to Legual, the bird has all together a noble and elegant gait.

FEMALES

This is an inhabitant of the *Isle of Rodrigue*, where it is not uncommon; but not met with in flocks, scarcely more than two being found together. It makes the nest in bye places, of leaves

PLACE AND MANNERS.

• These cannot be the only parts where they are found, and must have been imported into them from others, since it is said, that the *Portuguese*, who sirst discovered them, found neither land bird nor quadruped in either. See Hist. des Ois. vol. v. p. 280.

of the palm, a foot and a half in thickness; and lays one egg, bigger than that of a Goose. The male sits in his turn; and does not fuffer any bird to approach within two hundred yards of the fpot while the hen is fitting, which is feven weeks. The young is some months before it can shift for itself; the old ones, in the mean time, are affectionate to it, and faithful to each other afterwards, though they occasionally may mix with others of their kind. It is faid that a stone is always found in the gizzard: which perhaps, if the case be known, may turn out no more than may be found in all granivorous birds, ferving merely to prove it to be of that race. The young birds, though timid, are stupid enough to fuffer the approach of any one; but when grown up, are more fly, and will not be tamed. Two of them were shipped from Bourbon, but soon died, as they refused all suftenance. They are chased in the winter-season, viz. from March to September, being then fat, and the young birds are much esteemed for the table.

NAZARENE D.

L'Oiseau de Nazareth, Bus. Ois. i. p. 485.—Cauche Madag. p. 130. Oiseau de Nausée, Id. ibid.

DESCRIPTION.

THIS is a large bird, bigger than a Swan. The bill is a little bent downwards, and large: instead of seathers the whole body is covered over with a black down; but the wings are seathered, and it has some frizzled ones upon the rump, which serve instead of a tail: the legs are long and scaly, and there are three toes on each foot.

PLACE AND MANNERS.

This was met with in the *Isle of France*, and described as above by *Fr. Cauche*; who adds, that the *female* only lays one egg, which

which is white, and as big as a penny loaf, and that there is always found with it a white stone of the size of a Hen's egg—that it makes the nest of leaves and dry herbs, in the forests, on the ground; and that there is likewise found a grey stone in the gizzard of the young bird.

The three last-described birds seem to have much affinity to each other; if, on further observation, they do not prove the same species, differing only in age or sex.

GENUS LVIII. OSTRICH.

Nº 1. Black Oftrich.

THE bill in this species is strait, depressed like that of a Duck, and rounded at the end.

Wings small, in proportion to the size of the body, and useless for slight.

Legs naked above the knee.

Toes two in number, and both placed forwards.

This and the following, with a third, which late observations have proved to be of a far different family, were placed by Linneus under one genus. From the very dissimilar characters, we have thought right again to separate them, according to Brisson, who has thus done in his Ornithology.

BLACK O. PL. LXXI. Struthio Camelus, Lin. Syst. i. p. 265 .- Scop. Ann. i. Nº 160:

L'Autruche, Bris. Orn. v. p. 3. pl. 1. f. 1.—Bus. Ois. i. p. 398. pl. 29.— Pl. Enl. 457. (the female).

—Gent. Mag. xviii. pl. in p. 580.

Black Offrich, Brown. Illustr. pl. 16. (the male).

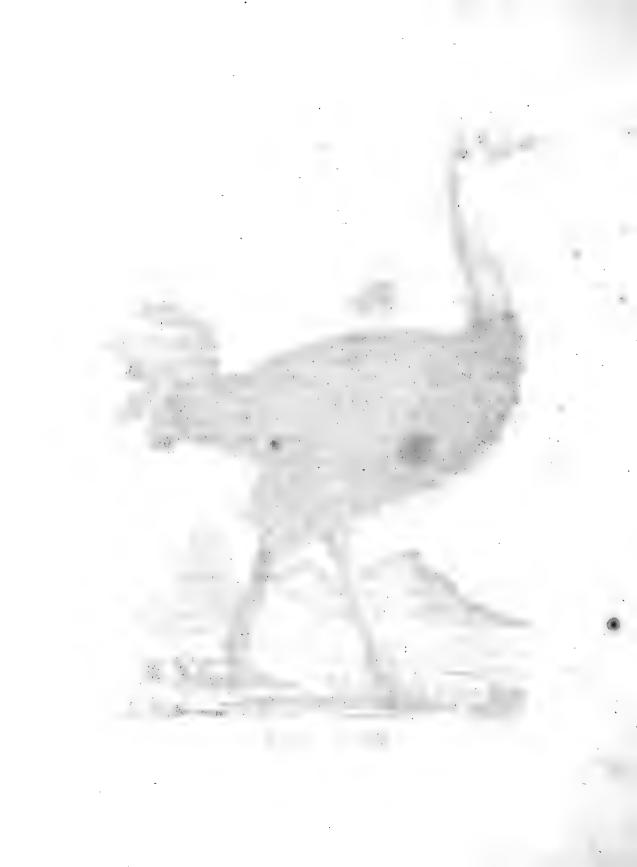

Lev. Mus.

Description.

THIS is, without doubt, the largest bird in the creation: it is near eight feet in length, and when standing upright is from

Black Ostrick!

from fix to eight feet in height *. It has a finall head, not much unlike that of a Goofe; the bill is also somewhat similar, but less depressed, and four inches and a half in length, horncoloured, with a dufky tip: irides hazel; eyelids befet with hairs: the head, and greatest part of the neck, are bare of feathers, of a flesh-colour, here and there beset with a few scattered hairs: the lower parts of the neck and body are covered with black feathers, which are fingularly loofe in their webs, and totally unlike those of any other bird: the quill feathers, and those of the tail, are of a perfect snowy white, some of them here and there fringed or tipped with black, and are long and beautifully waved in shape: on each wing are two spurs, about an inch in length; and on the breaft is a callous, bare, and hard fubstance, serving the bird to rest on when it first bends forwards to fit on the ground: the thighs and fides of the body are naked: the legs are strong, of a grevish brown, and furnished with two toes only, the outer one of which is very short, and without a claw.

The female differs from the male in having those feathers brown, which are black in the male.

This bird inhabits Africa, and the parts of Afia adjoining to it, with the feveral islands in the neighbourhood, and is in very great plenty about the Cape of Good Hope. The egg of this corresponds well with the fize of the bird, being as big as a child's bead, and white in colour †: the female is supposed to lay fifty

FEMALE.

PLACE AND MANNERS

[•] Two Ostriches were shewn in London in the year 1750; the male was ten feet in height, and weighed three hundred weight and a quarter.—See Gent. Mag. vol. xx. p. 536.

[†] See a figure in Klein, Ov. pl. 1.

or more in a season; these she is said to bury in the sand, and to be hatched by the heat of the sun only, and that the young run as soon as they come out of the egg: though others deny this; for Kolben says, that the male and female sit on them by turns, and that he has seen them hatching their eggs hundreds of times, and as often driven them off, and took the eggs, to feast himself and his friends (and some of them were near hatching); one of them proves a meal for three or four persons, and they are said to be very good. The young, he says, cannot run at first, but are supplied by the old ones with grass and water, and defended by them, till they can take care of themselves, so furiously as to render it dangerous to go near them at such times. If the eggs be touched, the old ones will forsake them *.

This bird, as well as fize, is also endued with ftrength in proportion; for instances are recorded where one has borne two men on its back, and has run along with them with the greatest ease †.

The food of the Oftrich is of the vegetable kind, grass, fruits, grain, &c. besides which it is frequently observed to swallow many foreign articles, as bits of iron, copper, glass, lead, and the like; but though this is often done with impunity, yet it is seen

^{*} Briffon allows that the Offrich scarce ever lose fight of the eggs; but that it is only in the more northern parts that the female has occasion to sit on them; in the torrid zone, the sun alone being fully sofficient. This may account for the positive affertion of Kolben, that the Offrich hatches her own eggs, as well as the opinion of others, who maintain the contrary.

[†] Adanson.—He thinks that their pace is swifter than that of the fleetest horse. Voy. Seneg. p. 87.—" Whilst I was here (at Vintain), I saw an Offrich with a man riding on it's back, who was going down to the fort, it being a present to the Governor." Moore's Trav. into Africa, p. 318.

in the end to prove fatal *, as it can by no means digest them. Some authors fay, that the young birds are pretty good food.

The natives catch them by following at a distance for two or three days, when the birds, satigued by being perpetually harrassed, and wanting time to take food, are very easily overtaken, and knocked on the head with clubs: others conceal themselves in a skin of one of these birds, and by that means approach near enough to surprize them; and it is not unusual to hunt them on horseback with dogs, and after overtaking them, the buntsman approaches near enough to apply the hooked end of a staff round the legs, which throwing them down, they are knocked on the head †, or taken alive.

The uses which the Ostrich is put to are various. The skins are very thick, and are substituted for leather by the Arabians: as to feathers, the value of them, and the purposes they are put to, need not be mentioned. The fat is of medicinal use among the Arabians, for the palfy and rheumatism, and is also prescribed inwardly. The eggs serve for drinking-cups, and other utensils, and are often set in gold for that purpose; they are very hard and durable, and equal in appearance to the most beautiful ivory. In the East also, the shells both of the Ostrich and Cassowary serve as a medicine §.

^{*} Pitsield's Mem. p. 226.

⁺ I remember to have seen a painting, which represented this method very justly.

^{† &}quot;They have a method of putting the dead body of the Offrich in motion, in fuch a manner, as to make the fat dissolve into a kind of oil, which they fell as a drug, and is called the fat of the Offrich." Pocock. Trav. i. p. 209.—Thevenot, in his Voyages, mentions the same thing.

[§] See Faun. Arab. Mater. Med. Nº 6.

GENUS LIX. CASSOWARY.

Nº 1. Galeated Cassowary.

HIS genus has a straight depressed bill, which is pointed at the end.

At the top of the head an elevated horn or helmet: on the middle of the neck, two carunculated pendent wattles.

Wings very small, without feathers, and useless for slight. Thighs bare of feathers above the knee.

Toes three in number, and all placed forwards.

GALEATED CASSOWARY. PL. LXXII. Struthio casuarius, Lin. Syst. i. p. 265. 2.—Frisch. pl. 105. Le Casoar, Bris. Orn. v. p. 10. pl. 1. f. 2.—Bust. Ois. i. p. 464.—Pl. Enl. 313.

Emeu, Eme, or Cassowary, Raii Syn. p. 36.—Will. Orn. p. 151. pl. 25.—
Albin. ii. pl. 60.—J. F. Miller, pl. 14.—Gent. Mag. xlii. pl. in p. 472.

DESCRIPTION.

THIS is a large bird, and not greatly inferior to an Offrick in bulk, though, from having a much shorter neck, is not near so tall: the length is about four feet, but from the bill to the end of the claws sive feet and a half. The bill is four inches and a half long, grey brown, a little notched at the end, the gape very wide: irides the colour of a topaz; eyelids beset with hairs: the nostrils oblong, placed near the end of the bill: the ears large and open: on the top of the head is a kind of helmet, beginning

Galeated Cafsowary.

beginning at the base of the bill, and reaching to the middle of the crown; this is three inches high, and one inch broad at the base, but gradually grows thinner, so as the upper part is not more than a quarter of an inch thick; this is yellowish at the back, but blackish on the fore part: the sides of the head are naked, being, as well as the neck, covered only with a wrinkled reddish skin, thinly beset with hairs, and tinged with a cast of both blue and purple: on the lower part on each fide, forwards, are placed two fleshy membranes, one inch and a half long, and three quarters broad, part red part blue, and take rife about the middle of the neck, where they are very slender: on the breast is a callous bare part, on which the bird refts its body when on the ground: the body in general is covered with brownish black loofe-webbed feathers, two of which arise from one shaft for the most part; on the rump these feathers are fourteen inches long at least, and hang downwards, in place of a tail, for the bird is destitute of one: the wing, or what is in the place of it, is not furnished with feathers, having only five bare shafts like the quills of a Porcupine, the longest ten or eleven inches, and of a dusky colour; at the end of the last joint a kind of claw: the legs have all the three toes placed forwards, and each furnished with a claw, which is almost straight, and pointed, the inner one the longest: the colour of the legs and toes greyish brown: claws black.

This species inhabits the eastern parts of Asia, towards the south, being found in the Molucca islands, those of Banda, Java, Sumatra, and parts corresponding, but no where in plenty, nor ever met with beyond the limits of the torrid zone. It cannot fly, but runs very fast. The egg is smaller and longer than Vol. III.

PLACE AND MANNERS that of the Ofirich, of a greenish grey, inclining to ash-colour, and marked with elevated * small deep green spots. The bird is very sierce in the wild state; grunts like an Hog; and kicks with the legs like an Horse.

The food, in the state of nature, is no doubt vegetable; for it will eat bread, apples, and such like, when in consinement; all which it swallows whole, not bruising it with the bill; and is said also to gorge stones, iron, and any thing which is offered to it, indiscriminately, like the Ofrich.

^{*} Linnaus calls the spots indented; Ova punctis excavatis. See a figure of the egg in K/siu. Ov. pl. 2.

SIZE of the Heron, but shorter in both neck and legs: length two feet eight inches. The bill is fix inches and a half long, very flat, and broadens out into the shape of a spoon at DESCRIPTION.

the

the extremity; it is in colour various, in some birds black, in others brown, and is also seen spotted; from the base to two-thirds of its length it is crossed with several indentations, the rising parts of which are dark-coloured: the tongue short, and heart-shaped: irides grey: the lore, round the eyes, and the throat, the skin is bare and black; that of the last very dilatable *: the whole plumage is white, though in some specimens the quills are tipped with black: the legs are black, or of a greyish brown colour: between the toes a membrane, connected to the outer one as far as the second, and to the inner as far as the first joint.

This bird is found in various parts of the old continent, and from the Ferro Isles †, near Iceland, to the Cape of Good Hope ‡: it frequents the neighbourhood of the sea, and has been met with on the coasts of France ||; at Sevenbuys, near Leyden, once in great plenty, annually breeding in a wood there §. The nest is placed on high trees near the sea-side. The semale lays three or four white eggs, powdered with a sew pale red spots, and of the size of those of an Hen. They are very noisy during breeding-time, like our Rooks; are seldom found high up the rivers, chiefly frequenting the mouths of them. Their sood is sish, which they are said not unfrequently to take from other birds **, in the manner of the Bald Eagle; also muscles, and other shell sish, being found in greatest numbers where these are plenty; and will also devour frogs and snakes, and even grass and weeds,

^{*} Decouv. Russ. i. p. 164. + Brunnich. ‡ Kolben.

DESCRIPTION. PL. LXXIV.

SIZE of a Turkey: length three feet four inches. The bill two inches and a quarter long, and black; the upper mandible a little gibbous at the base, the under shutting beneath it, as in the gallinaceous tribe: the nostrils oval and pervious, and placed near the middle of the bill: from the crown of the head springs a slender horn of more than three inches in length, and pointed at the end: the irides are the colour of gold: the plumage on the head, neck, and upper part of the body, is black, margined with grey on the first, and downy: some of the seathers wound the neck are likewise edged with the same: the under

parts.

Horned Screamer.

parts of the wings are pale rufous, appearing on the shoulders and edges of them, when closed: at the bend of the wing are two strong, sharp, horny, yellow spurs, one above another, the uppermost an inch and a half in length: the belly, thighs, and vent are white: the tail eight inches and a half long, and black: the legs stout and dusky: the fore claws moderately bent; the hind one nearly straight, not unlike that of a Lark, and one inch in length.

The female is faid to be like the male.

They are observed to be always met with in pairs, and if one dies, the other mourns to death for the loss. They frequent places near the water, make a large nest of mud, in the shape of an oven, upon the ground *, and lay two eggs, the fize of those of a Goose. The young are brought up in the nest till able to shift for themselves: they have but one nest in a year, which is in January or February, except the first eggs are taken away, in which case they make a second in April or May. The young birds are frequently eaten by the natives, though the colour of the flesh is very dark; that of the old ones is tough, and ill tasted. fome authors this species is faid to feed on crabs and birds, such as pigeons, poultry, and even to attack sheep and goats; but this is denied by others, who fay that its principal food is reptiles. In the stomach of one which M. Bajon diffected, there were only found berbs and feeds of plants; however he adds, that the bird has no gizzard. This is a rare species, is found in certain districts in Cayenne, Guiana, Surinam, and other parts of South America, chiefly in the marshes and wet savannas, and for the most

• Authors differ. Bajon says, that it makes the nest both in thickets, at some distance from the ground, and often among the rushes. Fermin tells us, that it builds on high trees. See Mem. sur Cay. and Descr. Surin.

FEMALE.
PLACE AND
MANNERS.

part near the sea. These should seem to be the birds mentioned by Ulloa*, which are called by the inhabitants of Quito, Dispertadores, or Awakeners, from their giving notice to others of the approach of danger; as on hearing the least noise, or seeing any one, though at a great distance, they rise from the ground, and make a loud chattering, like a Magpie, continuing the noise, and hovering over the object which caused the alarm, whereby the rest of the birds, taking the hint, are able in time to escape the impending danger. This screaming noise, which some authors relate as being exceedingly loud and terrible †, has occasioned Mr. Pennant to give the genus the name annexed to it.

In the Hunterian Museum is a fine specimen of this bird, brought from Cayenne.

CRESTED SCR.

Palamedea cristata, Lin. Syst. i. p. 232. 2. Le Cariama, Bris. Orn. p. 516. 1.—Bus. Ois. vii. p. 325.—Raii Syn. p. 96. 6.—Will. Orn. p. 276. pl. 51.

DESCRIPTION.

SIZE of an Heron. The bill short, bent like that of a bird of prey, and of a yellowish brown: irides gold-colour: on the forehead, just above the bill, is a tust of black seathers, variegated with ash-colour: the head, neck, and body, are grey, mixed with rusous and brown, most inclining to the last on the wings and tail: the wings are not surnished with spurs: the legs pretty long,

[•] Voy. vol. ii. p. 243.—Ulloa makes their fize no bigger than that of a Cock. He says, that the head is adorned with a tuft of feathers. Perhaps he may mean the next species.

[†] Terribili voce clamitans. Linnæus.

of a dull yellow: claws brown; the hind toe placed high up, so as not to touch the ground in walking.

This bird inhabits *Brafil*. *Linnæus* makes it to belong to the *Screamer* genus, perhaps from its cry, for it is faid to be heard far off, and is not unlike that of an *ben Turkey*. None of our later writers feem to have feen it, all of them relying on *Marcgrave* both for description and figure *. It is faid to feed on the same food as the *Heron* tribe: the flesh is good, and the bird by some kept tame.

PLACE AND
MANNERS.

American Sabirul.

hind-head are a few greyish feathers: the legs are strong, of a great length, and covered with black scales: wings and tail even at the end.

This bird is found in all the favannas of Cayenne, Guiana, and other parts of South America. It makes its neft in great trees, which grow on the borders; lays two eggs, and brings up the young in the nest till they can descend to the earth. The food is fish. The colour of the young birds is grey; the second year it changes to rose-colour, and the third pure white: they are said to be very voracious, taking great quantities of fish to satisfy them. In their nature are very wild. The slesh is good to eat, but that of young birds only, as the old ones are hard and oily.

M. Bajon is inclined to think that this bird is the American Ostrich of authors *; and indeed, on canvassing matters, I cannot with-hold my assent to the same opinion, for many reasons: in the sirst place, there is no sigure of that bird extant, writers referring to that of Nieremberg †, which is clearly the Cassowary: secondly, the very great similarity of names in the birds quoted by authors, viz. Nhandhuguacu, for the Ostrich of America, by Marcgrave ‡; Jabiru-guacu, and Nhandhu-apoa ||, for a greater Jabiru; again, Jabiru §, for a smaller species. These names seem to run much into one another; the last is also, according to Barrere, called Aouarou, by the inhabitants of Guiana. This author also likens

the Nhandhuguacu, or the supposed Offrich of America, to a Crane *.

It feems however to have gained universally the name of Oftrich by the Europeans, but unfortunately scarce any two have given the fame account: Marcgrave fays, it has three toes furnished with claws forwards, and one without a claw behind; Fermin, that it has only two toes, joined by a membrane +; but Bajon I assures us that it has four, all placed as in the Heron genus. However this be, we meet with birds called Oftriches, on the whole of the American continent, from Guiana to the most southern coast of the continent; at Rio Grande ||, about Buenos Ayres &. and fo on to the coasts of Patagonia **: indeed many other vovagers have mentioned, but none described the bird sufficient to ascertain the species. Dampier ++ also talks of Offriches being found to the fouth of Babia in great plenty, though not fo large as those of Africa, and found chiefly in the fouthern parts of Brafil, especially among the large favannas near the river Plate, and from thence further fouth, as far as the streights of Magellan.

- * Grus cinerea fer rivora; but adds, that it has somewhat the appearance of an Osrich. He calls it likewise, in other places, an Heron.
- † Descr. Surin. ii. p. 142.—He adds, that the bird has two spurs on each wing, like the Hedge-hog's quills, but confesses that he has never seen one. He is right, however, in saying that it stands from sour to sive feet in height.
 - 1 Mem. Sur Cay.

Pl. Enl. 869.

Tamatia, Raii Syn. p. 116. 12.—Will. Orn. p. 318. pl. 78.

Lev. Mus.

DESCRIPTION.

SIZE of the last. Head and crest the same: the upper parts, instead of ash-colour, are of a pale rusous brown: the tail rusous ash: the under parts wholly of a cream-colour: bill and legs yellow brown.

I find these birds vary much: in the first place, the crests are by no means of equal lengths; fince the cinereous one, mentioned by Buffon, had a shorter crest than the brown fort; whereas in those which came under my inspection, it was just the contrary; and in one specimen the crest was scarcely manifest: the bills too vary in colour; fome are black, others brown, and in one which I faw it appeared to have been yellow. If I may be allowed a conjecture, it is, that the cinereous, or first-described, is the male, the plain brown one the female, and the spotted variety of Brisson a young male; and that the crests of both are equal, when in an adult state. In the Pl. Enl. I observe a patch of grey in the middle of the greater wing coverts, which is not in any specimen that I have seen. The figure referred to in Brown is not good, being too short and squat; that in Hist. des Ois. much worse, though the bill and crest are well expressed: both those in the Pl. Enl. are sufficiently expressive; and it is to be hoped, that our representation will likewise give a just idea of so curious a bird.

This

This species, for I refer all that has been treated of above to one only, inhabits Cayenne, Guiana, and Brasil, and chiefly frequents such parts as are near the water: in such places it perches on the trees which hang over the streams, and, like the Kings-fisher, drops down on the fish which swim beneath. It has been thought to live on crabs likewise, whence the Linnaan name; but this is not clear, though it cannot be denied; yet we are certain that sish is the most common if not the only food.

PLACE AND
MANNERS.

GENUS LXIV. U M B R E.

Nº 1. Tufted Umbre.

BILL strong, thick, compressed, the upper mandible appearing to be composed of several pieces.

Nostrils linear, and placed obliquely.

Toes divided, furnished with a slight membrane at the base.

TUFTED U.

DESCRIPTION. PL. LXXVII.

SIZE of a Crow: length twenty inches. The bill is three inches and a half in length, and compressed on the sides; along each side of the upper mandible is a surrow, running lengthwise, about one-eighth of an inch from the ridge, beginning at the base, and sinishing about half an inch before it comes to the point of the bill, which is somewhat bent downwards; at the base of it are the nostrils, which are a mere slit, placed at a sharp angle with the surrow, and about half an inch in length; the under mandible is less deep at the base than the upper, grows smaller towards the end, is there a little truncated, and when closed, shuts in beneath the upper one; the colour of both brown: from the hind head springs a crest of loose feathers, exceeding sull, and sour inches in length; this, as well as the

Tufted Umbre.

whole body, is of an uniform brown colour, most like that of Umber, but rather palest beneath, and the neck seathers palest down the shafts: the wings and tail are even; the last is barred with three or sour bars of deeper brown, and tipped for about an inch with the same: the legs are long, and the thighs bare for two-thirds of the length; the colour of both dusky: between each toe is a membrane, about a quarter of an inch deep between the middle and outer, and somewhat less between that and the inner: the claws are small and bent.

I suspect the bird figured in the Pl. Enluminées to be a female, as there does not appear the least rudiment of a crest. The tail in this bird is of a paler brown, and crossed with five narrow bars of darker brown, with the tip of this last colour. That described by Brisson is also without a crest. The bird figured in Brown's work, gives a salse idea; it there appears a heavy, squate uncouth figure, the legs much too short, and the membrane between the toes nearly as much webbed as in a Duck.

At Sir Joseph Banks's is a most perfect specimen of the male, which came from the Cape of Good Hope. Buffon's bird came from Senegal.

Crown Bird, Voy. to Guinea, p. 250. pl. 11.

Br. Mus. Lev. Mus.

Description.
Male.

HIS is as large as the common Heron; the length two feet nine inches. The bill is two inches and a half long, ftrait, and of a brownish colour: irides grey: the crown of the head covered with foft black feathers, like velvet; on the hind part is a tuft composed of hair, or rather briftles, arising near each other at the base, and spreading out on all sides in a globular form; this is four inches in length, and of a reddish brown colour: the sides of the head are bare of feathers, being covered only by a fleshy membrane, of a reddish colour at the lower part, and in shape not unlike a kidney: on each fide of the throat hangs a kind of wattle: the general colour of the bird, blueish ash. The feathers on the fore part of the neck are very long, and hang over the breaft: wing coverts white; the greater ones incline to rufous, and those farthest from the body to black: the greater quills and tail are black, and the fecondaries chefnut: the legs, and the bare part above the knee, are dufky.

FEMALE.

The female is black, where the male is blue ash: and the wattles on the throat are wanting: the long feathers on the breast are also less conspicuous.

This

This beautiful fpecies is an inhabitant of Africa, particularly the Coast of Guinea*, as far as Cape Verd; at this last place they are said to be wonderfully tame, and will often come into the court-yards to feed with the poultry.

PLACE AND
MANNERS.

Why the name of Balearic Crane has been given to this bird, is not well afcertained, as it is certainly not met with in the Balearic Islands † at this day. These birds are often kept in our menageries, and, with shelter of nights, often live a good while. Their chief food supposed to be worms, and such other things as the Heron tribe usually feed on; also vegetables of all kinds. Often sleeps on one leg; runs very fast; and is said not only to sly well, but to sustain it for a long time together. The slesh of this bird is said to be very tough ‡.

neck behind, and all the under parts, to the breaft, black; on the last, the feathers are long, and hang downwards: the back, rump, and tail, and all the under part from the breast, are of a blueish ash-colour: behind each eye springs a tust of long white feathers, which decline downwards, and hang in an elegant manner: the quills and tail are black at the ends: the legs black.

PLACE AND MANNERS.

This species is found in many parts of Africa and Asia. In the first, has been met with on the Coast of Guinea*; but is most plentiful about Bildulgerid (the ancient Numidia), and Tripoli; from thence along the coasts of the Mediterranean Sea; and pretty common in Egypt †. They are also at Aleppo ‡, and in the southern plain about the Black and Caspian Seas; and are seen frequent beyond Lake Baikal, about the rivers Selenga and Argun, but never venture to the northward ||. In all places sound to prefer marshes and neighbourhood of rivers, as the food is fish, like most of the Heron genus.

It is frequently kept in menageries, being endowed with great gentleness of manners, added to its being an elegant bird. At various times puts itself into strange and uncouth attitudes, and especially those which imitate dancing: and Keysler mentions one in the Great Duke's Gallery, at Florence, which had been taught to dance to a certain tune, when played or sung to it §. The name this bird is known by in the east is Kurki, or Querky. Sometimes will breed in confinement: one is recorded to have

lived

<sup>Hift des Oif.
† Hasselq. p. 287.

lived twenty-four years at Versailles, which had been raised there*.

Grus Leucogeranos, Pall. Trav. ii. p. 714. 30. t. 1.—Georgi Reise, p. 171. Sibirian Crane, Art. Zool. p. 455.

SIBIR!AN CR.

THIS is a very large species, being four feet six inches high, when standing erect. The bill shaped like that of a crane, but bigger, and of a red colour; the mandibles serrated at the edges near the tip: the face naked beyond the eyes; rugose, of a red colour, and sprinkled with numerous rusous tubercles: irides white: the plumage white as snow, except the ten sirst greater quills, with the coverts of them, which are black: the scapulars shorter than in the Crane: tail pretty even, consisting of twelve feathers: legs long, red.

In old birds the hind part of the neck is yellowish: young birds of the first year are wholly of an oker colour; with the face, bill, and legs of a greenish brown.

This species inhabits the vast marshes and lakes in Sibiria, especially those about the Is him, and along the rivers Oh and Irtish. Makes the nest among the reeds, seldom accessible by man, upon rising green grassy tusts, made up of herbs and grass heaped together: lays two ash-coloured eggs of the size of those of a Goose, and spotted with brown.

These are shy birds, and always upon their guard against an enemy; having a centinel to warn them of an approach: on the least alarm cry aloud, not unlike the Swan, and sly off directly.

DESCRIPTION.

PLACE AND MANNERS.

· Hist. des Qis.

The

The sportsman finds, in course, much difficulty in approaching them within gunshot; for, as they stand near five feet high from the ground, they are enabled to espy him at a great distance. Sometimes indeed he approaches them under cover of a stalking-borse, or other object; at other times a small dog will divert their attention, as they will without fear attack the dog, while his master gets within reach. In breeding-time, however, they are more bold, as they will defend their young even against men, so as to make it dangerous to come near their haunts. The male and female said to guard the nest alternate.

The more northern parts are those of the summer residence, and to which they come in spring; departing south in autumn, probably winter about the Caspian Sea, and parts beyond. Fly always in pairs *. A bird similar to this, if not the same, we often see depicted in Chinese bangings. I rather think this, as I have more than once met with it in some drawings of Chinese birds.

The food is frogs, small fish, lizards, and such-like. The Russians know it by the name of Sterchi; and if the bird hinted at as Chinese be the same, it is called by them Tzew-ting-ha.

4. INDIAN CRANE. Ardea Antigone, Lin. Syst. i. p. 235.6. La Grue des Indes Orientales, Bris. Orn. v. p. 378.7. Greater Indian Crane, Edw. 45.

DESCRIPTION.

THIS is a larger bird than the common Crane, being in height five feet. The bill is of a greenish yellow, dusky at the tip: irides of a bright reddish hazel: crown of the head bare and

* Decouv. Ruff. ii. p. 145.

white;

white; on each fide of the head, about the ears, is a bare white fpot; the rest of the head, and a small part of the neck, covered with a fine red skin, and is also destitute of feathers: the plumage of the bird is ash-colour, lightest about the neck: the quills are black: tail and secondaries ash-colour; those nearest the body are pointed at the ends, longer than the quills, and hang over them: the legs, and bare space above the knee, are red: the claws white; the middle and outer toe connected by a membrane as far as the first joint.

This species inhabits the East Indies, also the Mongolian Defarts; from whence it migrates into that part of the Russian dominions which lies beyond Lake Baikal, keeping chiefly within the plains below the rivers Onon and Argun, which is the western extremity of the Gobean Plain*.

Lev. Mus.

DESCRIPTION.

HIS is a large bird, not unfrequently weighing ten pounds. and measures more than five feet in length. The bill is almost four inches and a quarter long, and of a greenish black: the forehead, to the middle of the crown, covered with black down or hairs; the hind part bare and red, with a few scattered hairs: on the nape, below this, is a bare space of two inches, and of an ash-colour: the sides of the head, behind the eyes, and the hind part of the neck, are white: between the bill and eyes, the cheeks beneath them, and the fore part of the neck, are of a blackish ash-colour: the lower part of the neck, and the rest of the body, fine ash-colour, deepest on the tail coverts: the greater wing coverts are blackish; and those farthest from the body, with the baftard wing, and quills, black: from the pinion of each wing springs an elegant tuft of loose feathers, curled at the ends, which may be erected at will, but in a quiescent state hang over and cover the tail: the legs are black.

PLACE AND MANNERS.

This species seems far spread, being met with in great flocks throughout northern Europe, and Asia; in Sweden, Russia throughout, and Sibiria as far as the river Anadyr, migrating even to the arctic circle. In Kamtschatka only seen on the southern promon-

tory:

tory*: are migratory, returning northward to breed in the fpring, and generally choosing the same places which had been occupied by them the season before †. In the winter inhabiting the warmer regions, such as Egypt ‡, Aleppo ||, India, &c.: also met with at the Cape of Good Hope, changing place with the season. In their migrations frequently sly so high as not to be visible; their passing only being known by the noise they make, being louder than any other bird §. In France they are seen spring and autumn; but for the most part are mere passengers. We are told that they frequented the marshes of Lincolnshire and Cambridgeshire, in vast slocks, formerly; but the case is altered, as of late none have been met with, except, a few years since, a single bird shot near Cambridge.

We are told that they make the nest in the marshes, and lay two blueish eggs. The young birds are thought very good food. They feed on reptiles of all kinds, and in turn on green corn; of which last they are said to make so great havock, as to ruin the farmers, wherever the slocks of these depredators alight.

Vol. III. G

^{*} Arct. Zool.—One of the reasons supposed to be, the want of frogs, toads, and ferpents; none being found in Kamtschatka.—Hist. of Kamtsch.—They have however plenty of lizards.

Hooping Crane, Cates. Car. i. pl. 75.—Edw. p. 132.—Art. Zool. N° 339.

Description.

ENGTH four feet fix inches; and to the end of the claws five feet feven inches. Bill fix inches, toothed at the edges near the end, and of a yellow brown colour: the top of the head, and under the eyes, covered with a red skin, beset with black hairs, which are placed so thick next the bill as to appear nearly black; this ends in a point nearly beneath the ears: behind the crown, on the nape, is a triangular black mark: the general colour of the plumage white; except the bend of the wing, which is of a pale rose-colour; the nine first quills are black; the tenth black and white; and the rest white: the legs, and bare

bare part of the thighs, black: on the rump the feathers are tufted, and hang curved downwards, as in the common Crane.

This is an American species, often seen at the mouths of the Savanna, Aratamaha, and other rivers nearer St. Augustine: in spring going to the north to breed, like the common Crane, and returning, like that bird, to the fouth in autumn. In the summer are found in Hudson's Bay, at which place they arrive in May, and retire in September; and are chiefly met with in unfrequented places, in the neighbourhood of lakes, where they breed. The nest is made on the ground, composed of grass and feathers. They lay two white eggs, like those of the Swan, and sit twenty days: the young are at first yellow, changing to white by degrees. These birds have a loud long note, which may be heard at a great distance: the food is chiefly worms and insects, which it searches for at the bottoms of ponds. The natives of Hudson's Bay call it Wapaw-uchechauk*.

BROWN CR.

LENGTH three feet three inches: weight feven pounds and a half. Bill three inches and three quarters, and dufky;

DESCRIPTION.

* For the vernacular name of this, as well as many other birds of North America, as also the manners of many species, I am indebted to the observations of Mr. Hutchins, of the Hudson's Bay Company, an intelligent and communicative Naturalist.

G 2

but

but the tip of the under mandible is pale flesh-colour: the top of the head covered with a red skin thinly beset with hairs: cheeks and throat whitish: the hind head and neck are cinereous: the upper part of the back, scapulars, and wing coverts, pale rufous, margined with brown; the lower and rump cinereous: the breast, belly, thighs, and sides, ash-colour, changing to white at the vent: the greater wing covert farthest from the body, blackish brown; those nearest the body grey, forming a band on the wing: the greater quills dark brown, with white shafts; the secondaries pale rusous: some of these last are long and narrow, and reach beyond the greater quills: the tail of a deep ash-colour: legs and bare part of the thighs black.

Scarce any difference between the male and female.

PLACE AND MANNERS. This is likewise a species peculiar to America; migrating at the different seasons, as the former. Seen by Kalm so early as the 7th of February, passing over New Jersey and Pensylvania; but he says they are seen in much sewer numbers than formerly. Come into the parts about Hudson's Bay in May: lay two eggs, and have the same manners as the last: will also eat corn, and at times do damage by eating the maize*. The sless is thought good by many. Called at Severn River the Blue Crane, by the natives Samak-uchechauk.

This is probably Willughby's Indian Crane †; which he fays is less than the common one, but the bill larger in proportion: the top of the head red, set with long hairs: the body ash-colour; and the tail short, being hid by the feathers. Ray supposes it to be the Toquilcoyotl of Hernandez, which is a Mexican species ‡.

Argill,

^{*} Art. Zool. † Orn. p. 275.

Argill, or Hurgill, Ives's Voy. p. 183.

8. GIGANTIC CR.

DESCRIPTION.

THE bird here quoted seems to be of the Heron tribe, and is a very large species; from tip to tip of the wings measuring sourteen seet ten inches; and from the tip of the bill to the claws, seven seet and a half: the bill sixteen inches round at the base, of different colours, and nearly of a triangular shape: the seathers of the back and wings very strong, and of an iron-colour; those of the breast long: over the belly a great deal of down, of a dirty white: the legs and half the thighs naked; the naked parts full three seet in length.

This monster, as *Ives* terms it, inhabits *Bengal*, and is also found at *Calcutta*; at the last place called *Hurgill*, or *Argill*. It majestically stalks along before one, and appears at first like a *naked Indian*. The common opinion is, that the fouls of the *Bramins* possess these birds. "On opening one of these, a *Terapin*, or land Tortoise, ten inches long, was found in its craw, and a large male *black cat* was found intire in its stomach *."

I have scarce a doubt of the above being the same as a species remarked by Mr. Smeathman in Africa, while resident there; an adult one of which will often measure sull 7 feet, when standing erect. He describes the plumage much the same as in Mr. Ives's bird; adding, that the gape is monstrously wide: the head covered with white down, thinly dispersed, appearing not unlike a greyheaded man: on the middle of the neck before, a long, conic

PLACE AND MANNERS.

membrane,

^{*} In Sumatra is faid to be a great variety of the Stork kind; some of a prodigious size, and otherwise curious; as the Boorong Cambing and Booring-onlar.
—See Mar/d. Sumatr. p. 98.

membrane, like a bladder, sprinkled very thinly with short down, rising or falling as the animal moves the beak, and always appearing inflated.

These birds are met with in companies; and when seen at a distance, near the mouths of rivers, coming towards an observer, which they do with the wings extended, may well be taken for canoes, upon the surface of a smooth sea: when on the sand banks, for men and women picking up shell-sish or other things on the beach.

One of these, a young bird, about five feet in height, was brought up tame, and prefented to the Chief of the Bananas, where Mr. Smeathman lived; and being accustomed to be fed in the great hall, foon became familiar; duly attending that place at dinner-time, placing itself behind its master's chair, frequently before any of the guests entered. The servants were obliged to watch it narrowly, and to defend the provisions with switches in their hands; but, notwithstanding this, it would frequently fnatch off fomewhat or other, and was known once to have purloined a whole boiled fowl, which it swallowed in an instant. Its courage is not equal to its voracity; for a child of eight or ten years old foon puts it to flight with a fwitch, though at first it feems to stand upon its defence, by threatening with its enormous bill, widely extended, and crying out with a loud hoarfe voice, like a bear or tiger. It is an enemy to small quadrupeds, as well as birds and reptiles, and destroys fowls and chickens, though it dare not attack a hen with her young openly: it preys also on rats, young kittens, and the like; and has been known to fwallow a cat whole: a bone of a shin of beef being broken asunder, serves it but for two morsels.

The

The individual above mentioned used to fly about the island, and rooft very high among the filk cotton trees; from whence, at two or three miles distance, it could spy the dinner carrying across the yard; when, darting from its station, it would enter promiscuously with the women who carried in the dishes. When fitting, it was observed to rest itself on the whole length of the hind part of the leg. It fometimes flood near, for half an hour after dinner, with the head turning alternately, as if liftening to the conversation; and during this time would every three or four minutes void the excrements, which were liquid, and whitish; and took care always to do this on his legs, by wheeling the back parts round over one or the other, and this regularly on different legs; for if he had muted on the left leg last, he would be fure to do the same on the right the next time; never making any miftake.—As to the rest of its manners, such as incubation, &c. my friend is filent.

coverts,

coverts, and quills, are black: the skin, legs, and bare part of the thighs, are red*.

Male and female much alike.

PLACE AND MANNERS.

This familiar species inhabits in turn the various parts of the old continent; but avoiding alike the extremes of heat and cold, being never met with between the tropics, nor scarce ever feen more north than Sweden, or in Russia beyond 50 degrees. It never frequents Sibiria, though fometimes feen in Bucharia, where it makes its neft; tending towards the fouth in autumn, to winter in Egypt. It has fcarce ever been met with in England †; though it is well known, that in Lorrain and Alface, in France, as well as in Holland, they every where build on the tops of the houses, and the good-natured inhabitants provide boxes for them to make their nests in; this they not only do, but are particularly careful that the birds fuffer no injury, refenting it as done to themfelves. At Bagdad Ives faw a neft of these, June 13, on a dome of a decayed mosque; and says that hundreds are to be seen on every house, wall, and tree, quite tame ‡. At Persepolis, or Chilmanar, in Persia, the remains of the pillars serve them to build on, "every pillar having a neft of them ||." They are common at Aleppo §; and in plenty at Seville ** in Spain. Thought

to

^{*} The bill and legs are fometimes brown. Salerne.—Such a variety I recollect to have feen in the collection of that well-informed naturalist, Marmaduke Tunsfall, Esq; whose liberal communications on Ornithology I beg leave to acknowledge.

⁺ Two instances only are on record: Willughby mentions one being shot in Norfolk; and Albin a second in Middlesex.

I Ives's Voy. p. 299, 307. | Fryer's Trav. p. 251. § Russel Alep. p. 69.

^{**} In the winter feafon Storks are very numerous in Seville; almost every tower

to have two broods in a year; the first towards the north, the latter one in the warmer places. Are seen in vast slocks during their migrations. Shaw saw three slights of them leaving Egypt, passing over mount Carmel, towards the north-east, in the middle of April, each of them half a mile in breadth, and they were three hours passing over *. Said to remain the whole year in Japan †, and, if I mistake not Hasselquist; at Alexandria likewise.

The female makes a large nest, composed of sticks; and lays from two to sour eggs, which are of a dirty yellowish white, the size of those of a goose, but a trisle longer. The young are hatched in a month, and at first are brown: the male and female said to watch them by turns, till they are sit to take care of themselves. The Stork sleeps on one leg, and snaps with its bill in a singular manner ||. The food consists of frogs, snakes, and other reptiles: hence the veneration of all sects for this useful bird, which frees them from these pests; added to the sless being

in the city is peopled with them, and they return annually to the same nests. They destroy all the vermin on the tops of the houses, and peck up a great number of snakes; so that they are welcome guests to the inhabitants, and looked upon with particular veneration.—Dillon Trav. p. 308.

* Trav. p. 428.—Some persons have supposed this to be the Ibis of the antients, with full as good reason as any other bird. It is certain that the Egyptians embalmed the bodies of birds; and it is as certain that birds of the Stork kind make a part of them. That in Edw. pl. 105, seems to be that of the Ibis or Curlew genus.—Compare Pococke Trav. i. pl. 64. G.

† Kampfer. ‡ Voy. p. 9.

II In doing this the head is turned backwards, the upper part of the bill placed on the rump, and the under, fet into the quickest motion, made to act on the other.—Ives's Voy. p. 307.

H

no temptation as a food, as it is allowed on all hands to be unfavoury.

AMERICAN ST. La Cigogne d'Amerique, Brif. Orn. v. p. 369. 3. Le Maguari, Buf. Oif. vii. p. 275. Ciconia Americana, American Stork, Raii Syn. p. 97. 3.—Will. Orn. p. 287.

DESCRIPTION.

SIZE of the last. Bill nine inches long; the base half of a yellowish green, the rest of a blueish ash-colour: irides silver-coloured; orbits red; and between the bill and eyes a bare skin of the same colour: the plumage in general is white: the seathers on the lower part of the neck before, long and loose: the tail is white; but the seathers above it are black: the greater scapulars, greater coverts, and quills, are also black; and those nearest the body as long as the quills: the legs, and bare part of the thighs, are red: claws broad and flat.

PLACE.

This species is found in the warmer parts of America, especially Brasil, and is accounted good food: is said to snap with the bill, like the common Stork.

BLACK ST.

Black Stork, Raii Syn. p. 97. A. z.—Will. Orn. p. 286. pl. 52.—Albin, iii. pl. 82.—Ar&. Zool. p. 456.

Description.

SIZE of a small Turkey: length two feet nine inches. Bill five inches and a half long, of a greenish grey, with a whitish tip: the top of the head is brown, glossed with violet and

and green: throat and neck brown, dotted with white, but the lower part of the neck is gloffed with violet, and dotted with grey brown*: back, wing coverts, and fcapulars, violet brown, gloffed with green: rump plain brown: from the breaft to the vent white: quills brown, gloffed with green and violet; those nearest the body, narrow, and as long as the greater when the wing is closed: tail rounded in shape: legs of a dull red: claws broad and flat.

This species inhabits many parts of Europe; but is less common than the white, and like that migrates south in autumn. It is not familiar with man; but retires to the thick forests and marshes, at a distance from habitations, in order to breed, being a solitary bird. Is pretty common in Poland, Lithuania, Prussia, and Switzerland; and migrates much farther north than the white species. In the more temperate parts of Russia and Sibiria not uncommon; and is plentiful all along the Don. It perches on trees, and makes the nest on them in the depths of forests. From its being less common, we hear of it among authors seldomer than the former: it is however ranked by authors among those frequenting the Caspian Sea; and by Russel as a bird of Aleppo. Like the White Stork, it feeds on reptiles and fish: the stell is said to be no better tasted.

This is not constant; some birds have no spot. Brisson.

DESCRIPTION.

HIS elegant species is in length twenty inches. The bill is stout, three inches and three quarters long; black, with the base yellowish: irides orange: lore, and round the eye, green: the crown of the head is greenish black, extending a little way down the back part of the neck, and there ends in a point: from the hind head spring three very narrow feathers, near six inches in length, of a pure white, with dusky tips: the hind part of the neck, and sides, are ash-colour: the upper part of the back dull

green:

^{*} In Willughby's plate the bill is curved, not much less than in the bird called Ibis, in pl. 49. I therefore suspect that this bird does not belong to the Heron genus.

green: the lower part, rump, wings, and tail, pale ash-colour: the forehead, and rest of the body, white: legs yellowish green: claws dusky.

Ardea Grisea, Lin. Syst. i. p. 239. 22. Le Heron gris, Bris. Orn. v. p. 412. 9. Femelle du Bihoreau, Pl. Enl. 759. + NIGHT H.
FEMALE.

SIZE of the last. Bill the same: lore white: crown of the head brown and gloffy: the upper parts of the body the fame, but with a tinge of grey; the hind parts of the neck paleft, and ftreaked with darker brown down the shaft; and the lower part of the back and rump almost grey: over the eye, from the nostrils, is a whitish streak, mixed with brown: the cheeks are of a mixed white and brown colour: the chin is white; but the fore part of the neck is grey, marked with a yellowish streak down each shaft; the feathers towards the bottom of the neck longer than the others: the rest of the under parts grey, growing white on the belly and vent: the wings are grey brown, ftreaked with yellowish white; some of the greater coverts tipped with white: the quills are cinereous grey; and the eighteen first have white tips: tail the fame colour; all, except the two middle feathers, marked more or less with white at the ends: legs grey brown.

DESCRIPTION

This bird is common both to Europe and America; but, except in a fingle instance, I do not hear of its having been met with in England*: it is most likely not met with so far north as Sweden,

PLACE AND MANNERS

^{*} One of these, a male, is in the Leverian Museum; which was shot, not many miles from London, in the month of May, 1782.

or Linnæus would have mentioned it in his Fauna. Pretty common in Russia, particularly on the river Don, where it builds on trees: is met with also at Astrachan during summer *: formerly in plenty at Sevenhuys, near Leyden, along with the Spoon-bills and other birds †; but the wood that grew there is now no more ‡. It migrates, like many of the species, being found at Aleppo; and I have often seen sigures of it in Chinese drawings ||. In America it is met with at New York and Rhode Island, and probably common to other parts of that continent. It is said to make the nest in the alders, and to lay three or four white eggs; but sometimes builds among the rocks. The food consists of frogs, reptiles, and fish; and is said not to be palatable food.

The Germans call it Nachtrab, or Night Raven, from its uncouth, rough voice, like a person straining to vomit §. By the Russians it is called Kwaka, from its cry.

← JAMAICA NIGHT H. Description. LENGTH one foot eleven inches. Bill four inches long, and dusky; the upper mandible bends a trifle downwards at the point; the colour dusky; the ridge of the upper part blackish: the irides pale straw-colour: between the eye, and round it, bare and greenish: the head is somewhat crested; the crown dark brown; each feather is streaked down the middle with ferruginous: neck the same, but the colours duller and paler: chin and throat white: neck feathers pretty loose: the

* Dec. Ruff. ii. p. 146. + Willugbby. # Brit. Zool.

^[] I met with a specimen of the semale, at Sir Joseph Banks's, which came from China; but in this every feather of the wings was tipped with white, and the spots were more distinct than in the European species.—Said also by Pernetty to have been met with in Falkland's Isles. See Voy. aux Malouin. vol. ii. p. 26.

[§] Willughby.

upper part of the back darker than the rest; the rest of the back, and scapulars, yellowish brown; some of the last tipped with white: wing coverts like the back; but the lower order of them much paler, giving the appearance of a broad bar: all the coverts white down the shaft, which spreads out to the tip, and forms a longish triangular spot: quills the colour of the lesser coverts: the primaries and bastard wing tipped with white; the secondaries plain: breast and belly white, streaked with obscure pale brown: vent white: legs brown.

This bird I received from Jamaica, where it goes by the name of Clucking Hen*: it frequents woods, contrary to the generality of the genus, which haunt moraffes: is a scarce bird, and very shy. Has a great affinity to the female Night Heron, but is larger.

PLACE.

LENGTH twenty-two inches. Bill strait, shaped like that of the Night Heron, and black: between the eye and bill bare, and green: irides yellow: from the nape behind spring three long feathers, as in the abovementioned bird: the crown of the head is black: over the eye, between that and the crest, a streak of white: the general colour of the plumage ferruginous, inclining to brown; neck the palest; the feathers of it loose on the fore part: breast, belly, and under parts, white: legs yellow: claws dusky.

Inhabits New Caledonia +.

CALEDONIAN NIGHT H.

DESCRIPTION.

PLACE.

- Dampier observes, that there are many clocking Hens in the Bay of Campeachy, and elsewhere in the West Indies, which make a noise like our brood Hens, when they have chickens; but does not determine the species.
- + See Cook's Voy. vol. ii. p. 111. pl. 50.—I do not find it there described, but Dr. Forster was so obliging as to supply that desect.

16. CAYENNE NIGHT H. Le Bihoreau de Cayenne, Buf. Ois. vii. p. 439 .- Pl. Enl. 899.

DESCRIPTION.

THIS is as big as the European species, but more slender, and the legs longer: length twenty-one inches. The bill black: the lore pale green: the crown of the head white; and a streak of white from the nostrils passes beneath the eye, towards the hind head; the rest of the head is black, which ends in a point on the back part of the neck: from the back part of the head fprings a crest, composed of six long feathers of unequal lengths; half of them white, the rest black: the general colour of the rest of the plumage a blueish ash-colour, but darkest on the back and wings, which are marked with a blackish streak down the middle of each fhaft: the quills are black: it is high mounted on its legs; and the thighs are bare a great way up: the colour of the bare part and legs is yellowish.

PLACE.

This is found at Cayenne.

Description.

THIS is an elegant species, and is somewhat less than the Heron: length two feet fix inches. The bill brown, beneath inclining to green: irides yellow: the head feathers are long; and

and those of the neck loose and waving: the crown of the head black; the lower jaw on each side dusky: the plumage in general is beautifully variegated; the ground a ferruginous yellow, palest beneath, marked with numerous bars, streaks, and zigzag lines of black: the legs are pale green; claws long and slender; and the inner edge on the middle claw ferrated.

The female is less, darker coloured, and the feathers on the head and neck less flowing than in the male.

This is a common bird in our islands, and we believe in most of the temperate parts of the continent: in fome of the colder migratory*; with us it remains the whole year. Frequents marshy places, and especially where reeds grow, among which it makes the nest, in April, which is chiefly composed of a bed of rushes, &c. The female lays four or five eggs, of a pale greenish ash-colour; the young are hatched in twenty-five days. It is an indolent bird, ftirring very little in the day, unless diffurbed; though, if once roused, is not difficult to shoot, as it flies heavily. In the evening, after fun-fet, is feen to foar aloft in a spiral ascent, till quite out of sight, and this chiefly in autumn, making a fingular kind of noise: it has also another noise, like that of a bellowing Bull, beginning in February, and ceasing after breedingtime; but this is done while on the ground. If attacked by dogs or men, defends itself well; and is faid to strike at the eyes of the enemy. The food is frogs, mice, and other reptiles, which it swallows whole, as well as fish; as I well remember to have found two middle-fized trouts in the stomach of one, perfeetly whole. It is reckoned pretty good eating.

Vol. III. I

FEMALE.

PLACE AND MANNERS.

^{*} For instance Sweden .- Amen. Acad. iv. p. 588.

17. Var. A. Le Butor de la Baye d'Hudson, Bris. Orn. v. p. 449. 25.—Buf. Ois. vii. p. 430. Bittern from Hudson's Bay, Edw. pl. 136.—Phil. Trans. vol. lxii. p. 410.

DESCRIPTION.

THIS is smaller than the common Bittern, and is two feet three inches in length: it is very like that in all respects; but the ground colour is darker, more inclined to brown, and the bill longer than in our species.

PLACE AND MANNERS.

This inhabits Hudson's Bay, and appears a mere variety of ours. It appears at Severn River the beginning of June, and makes the nest in the swamps, laying four cinereous green eggs. The nest is composed of water plants, placed on some dry spot among the long grass. The young are at first black. Departs in October. Said to be delicate eating. The natives call it Mokobosue.

18. GREATER B. Le grand Butor, Bris. Orn. v. p. 455. 28.—Buf. Ois. vii. 422. Greater speckled, or red Heron, Raii Syn. p. 100. 13.—Will. Orn. p. 283.

DESCRIPTION.

THIS is confiderably bigger than the common Bittern: length three feet nine inches. Bill eight inches long, and yellowish: irides yellow: lore, and space round the eye, naked and yellow: feathers of the head black, and pretty long: the upper part of the neck and body, wings and tail, cinereous brown: sides of the neck rusous, marked with a streak of black: throat and fore part of the neck white, dashed with black, and rusous-white streaks: feathers on the breast long and pendent: the colour of the under parts of the body rusous: scapulars the same, and very narrow: thighs white: legs brown.

Found

Found in the marshes of *Italy*, and in some parts known by the name of *Ruffey**. Said also to inhabit *Astrachan* during the summer season +.

PLACE.

Ardea botaurus major, N. C. Petr. xv. p. 482. No 22. t. 24. (Gmelin.)

18. VAR. A.

ENGTH four feet fix inches. Bill yellow: eye-lids naked, of a yellowish blue: irides saffron-colour: head black, and crested: temples yellow, partly dotted with black: head beneath white: neck chesnut, marked with three narrow longitudinal bands of black; the lower part chesnut, spotted with black, and black and white: back of a deep ash-colour; the seathers on the lowest part long, broad, and red; the longest white at the ends: rump grey brown: under parts of the body black and red mixed: wing coverts cinereous; some of the seathers tipped with yellowish: edge of the wing ferruginous: quills and tail black: thighs chesnut: legs reddish brown: claws pale brown; middle one serrated within.

DESCRIPTION.

This species, if distinct from the last-described, is found at Astrachan in May, migrating from the south. It lays three smooth plain green eggs, the size of those of a Hen; and is found in the marshes, where the other Herons resort.

PLACE.

^{*} Aldrow. Av. iii. p. 408.—This author suspects it to be a mixed breed between the common Heron and Bittern.

⁺ Dec. Ruff. ii. p. 146.

RUFOUS B.

Le Butor roux, Bris. Orn. v. p. 458. 29.—Buf. Ois. vii. p. 425. Ardeæ stellaris tertium genus Aldrov. Raii Syn. p. 100. 12. Aldrovandus's 3d sort of Speckled Heron, Will. Orn. p. 283. Quoimeau, Salerne Orn. p. 315.

DESCRIPTION.

A TRIFLE bigger than the Swabian Bittern. Bill blackish, horn-coloured beneath: irides yellow: crown of the head black; the rest of the head, throat, and neck, ferruginous: back, scapulars, and rump, blackish: from the breast to the vent pale rufous: wing coverts ferruginous and white, mixed: greater quills blackish, the lesser ones ferruginous: tail blackish: legs brown.

PLACE.

This is faid to inhabit the neighbourhood of *Bologna*. Salerne thinks it may probably prove the bird called *Quoimeau*, which is not unfrequent about *Sologne* in *France*. This description was from a young bird; and, if so, it is scarcely clear whether it was a distinct species or not.

SWABIAN B.

Le petit Butor, Bris. Orn. v. p. 452. 26.—Buf. Ois. vii. p. 423.

DESCRIPTION.

THIS is much less than the common Bittern. The irides whitish: bare space between the bill and eye yellow: the head, and upper part of the neck, breast, belly, sides, rump, and tail coverts, are rusous, striated with brown: the back is much the same; but the striæ are broader, and more numerous: throat and fore part of the neck white: upper part of the thighs brownish white: quills pale brown, crossed with bars of deeper brown: tail whitish: legs pale yellow.

PLACE.

Inhabits the banks of the Danube.

Le Butor rayé, Bris. Orn. v. p. 454. 27.

brun rayé, Buf. Ois. vii. p. 424.

RAYED B.

SIZE of the last. Bill brown, yellowish beneath: lore naked and yellow: all the upper parts of the body, the belly, and vent, crossed with lines of brown, black, and pale rusous, mixed irregularly, so as at a distance to appear wholly brown: the fore part of the neck and breast are whitish: legs and claws grey.

DESCRIPTION.

Found on the banks of the Danube, with the last.

PLACE.

Le petit Butor de Cayenne, Buf. Ois. vii. p. 430.—Pl. Enl. 763.

ZIGZAG B.

DESCRIPTION.

Length thirteen inches. Bill brown; under mandible pale: lore blueish: the whole plumage is of a yellowish or rusous grey, crossed with narrow streaks of black brown; these are pretty regular on the back, but elsewhere undulated, and in a zigzag manner: the top of the head is black, and the feathers on the neck exceeding full, so as to appear nearly of the same size as the body: the fore part of the neck is palest, and has sewer brown markings than the upper part: and the belly and thighs have only a few irregular zigzags: the legs are yellow.

This is a most beautiful species, and is found at Cayenne.

Clucking Hen, Brown Jam. p. 478.—Damp. Voy. iii. pt 1. p. 75?

DESCRIPTION.

ENGTH two feet eight inches. Bill black: irides yellow: the head and neck are brown, marked with small black spots: throat and fore part of the neck white, marked with longitudinal black and brown spots: the upper and under parts of the body, and lesser wing coverts, are blackish, spotted all over with yellow; but the greater coverts are plain: the quills and tail are blackish: the legs brown.

PLACE AND MANNERS.

This is found in various parts of South America. A different description is given of this bird in the Gent. Mag.*; which observes, that it is a quarter less than in the common Heron. The bill reddish yellow: head and upper part of the body deep orange red, finely barred with black: chin whitish red: fore part of the neck pale red, with oblong black spots; the feathers long and loose: belly white, spotted with yellow: thighs barred with dusky: quills black, tipped with white: rump and tail coverts dashed with white, black, and yellow narrow lines: tail black, crossed with a few white lines, and tipped with the same: legs dull rust-colour.

A fecond differed in some respects. The long neck feathers were white on their lower parts: breast and sides white, marked

• The description likewise in Brown's Ill. differs not materially from this.

OI

with

with regular rows of large black spots: middle of the belly white: quills like the other, and besides spotted on the exterior web with white: legs pale brown.

The above were probably male and female, and inhabit the lakes and rivers of the hot parts of North America and new-ceded ifles of the West Indies. Feed on fish, yet are reckoned good eating, especially the young birds. The fowlers watch in the sedges, and shoot them.

L'Onoré, Buf. Ois. vii. p. 431.—Pl. Enl. 790. Heron Tigré, Fermin Surin. ii. p. 151. Lev. Mus.

+ TIGER BITTERN.

THIS is about two feet fix inches in length. The bill is greenish: irides yellowish: the top of the head black: the throat and sides of the neck pale rusous, marked with regular spots of black; and the neck feathers very long: the rest of the plumage deep rusous, marked with black, like the skin of a tiger: the chin is white: the under parts much as the upper, but the ground yellowish white: vent plain white: the tail black, barred with four narrow bars of white: legs green.

This inhabits Cayenne, Surinam, and other parts of South America, and does not appear to be a very rare species, as I have met with several. It lays seven or eight rounded whitish eggs, spotted with green; making the nest on the ground. It hides itself in the reeds, like our European Bittern, and frequents the same kind of places. It is a most beautiful species. It seems much allied to the last.

DESCRIPTION.

PLACE AND MANNERS.

64

LINEATED B.

L'Onoré rayé, Buf. Ois. vii. p. 432.—Pl. Enl. 860. Lev. Mus.

DESCRIPTION.

fix inches. The bill and lore are both blue; the last bare the whole breadth of the base of the mandibles: the upper parts of the head and neck are bright rusous, crossed with numerous brown lines: down the fore part passes a streak of white, beginning at the chin; this is bounded half way by dashes of brown, and the lower half mixed along with the white itself: the upper parts of the body are crossed with fine waved lines of rusous, pale yellow, and brown: the under parts of the body dirty white: quills and tail black: legs yellow.

PLACE AND
MANNERS.

This frequents the banks of the rivers at Cayenne, with the laft: mostly found single. Like our species, when one is shot it makes great defence, throwing out the neck suddenly, when it can strike at the enemy with advantage, especially at the eyes. One of these kept tame, was of singular use in destroying rats, watching them with all the attention of the house cat, and even with better success.

FEMALE.

Le Blongios tacheté, Bris. Orn. v. p. 497. 47.—Buf. Ois. vii. p. 395. Little Brown Bittern, Edw. pl. 275.

DESCRIPTION.

SIZE of the former. The crown blackish green: the feathers on the upper part of the body brown, margined with pale rusous; beneath, the same, but paler, and the feathers more deeply margined with rusous: forehead edged with chesnut: the feathers on the fore part of the neck long, as in the other: belly white: tail blackish green, margined with sulvous at the ends: legs greenish.

PLACE AND
MANNERS.

This and the former are by most authors considered as the same species, of which the last is supposed to be the female. They have been sound frequently in Switzerland, and met with also in Arabia, but scarce in other parts. We learn in the British Zoology, that the male has been once shot, perched on one of the trees of the public walks in Shrewsbury; and another killed in 1773, near Christchurch in Hampshire, now in the Museum of Mr. Tunstall. In France they are likewise rare, only now and then one being met with by accident. We are told that they are common on the river Coic, near Aleppo; and that they are observed frequently to stand with the neck stretched strait upwards.*

Br. Muf. Lew. Muf.

DESCRIPTION.

GIZE of a small Fowl: length eighteen inches. The bill is greenish brown; the under mandible yellowish next the base; between that and the eye bare and vellow: irides yellow: the crown of the head of a blackish gold green, mixed with a gloss of copper in some lights, and the feathers elongated, forming a handsome crest: neck ferruginous bay: chin and throat white: the rest of the neck before streaked with white: in the direction of the under jaw, beneath it, a ferruginous streak: back, tail, and wings, dusky brown, with a tinge of lead-colour: the lesser wing coverts and prime quills the colour of the back, edged with buffcolour: the middle and larger wing coverts gloffy dark green, with ferruginous edges: the breaft and belly dufky: the feathers on the lower part of the neck are narrow, and fall over the breast; those of the back the same, covering the rump: the legs greenish.

FEMALE.

The female has the crown dusky; the feathers of it scarcely elongated: feathers of the neck pale brown, streaked with white: back and scapulars brown; the last marked with white 9 just just at the tip: all the wing coverts have a triangular white spot at the tip: the last row of wing coverts are tipped like the others, and margined with the same: secondary quills dusky green, with pale edges; the greater brown, glossed with green, and tipped with white: the under parts of the body pale ash-colour: bill and legs as in the male.

Inhabits New York, and other parts of North America; as also Jamaica, and other West India Islands. I have received these from both places, and observe that the Jamaica one is highest coloured. Supposed to breed in Carolina, as they are found there only in summer. It feeds on small sish, frogs, and crabs. Sits with the head drawn in between the shoulders for a long time together, on a branch of a tree hanging over the water; from whence it may possibly dart on a fish, in the same manner as the belted Kingsisher*; which likewise is known by the name of Crabcatcher in Jamaica.

Le Crabier des Philippines, Bris. Orn. v. p. 474. 38. pl. 37. fig. z. Le petit Crabier, Bus. Ois. vii. p. 395.—Pl. Enl. 898.

DESCRIPTION.

SIZE fmall: length eleven inches. Bill greenish yellow: between that and the eye bare, green: the top of the head, and all the upper parts of the neck, rusous brown, most inclining to brown on the head: the back is crossed with transverse rusous and brown lines: the wings black, edged with rusous white: quills and tail black: the fore part of the neck dirty rusous white: belly, thighs, and vent, white: legs yellow.

PLACE.

Inhabits the Philippine Isles.

36. SQUAIOTTA H. DESCRIPTION.

ENGTH about eighteen inches. The bill three inches and three quarters, yellow, with a black tip: between the bill and eye, bare and yellow: it has a tuft on the head confifting of thirty feathers, the middle one white, the outer ones black: besides these, the general colour of the plumage is a fine chesnut: the scapulars are long and narrow, and white at the base: legs green.

PLACE.

Inhabits Italy, about Bologna, where it is called Squaiotta.

Le Crabier marron, Bris. Orn. v. p. 468. 34.

CHESNUT H.

SIZE of a Crow. The bill four inches in length, and brown: irides pale yellow: the head and upper parts are chefnut: the under parts of a dirty white: there is also a streak of pure white down all the fore part of the neck and breast, quite to the belly: the wing-coverts incline to blue: the quills black: tail chesnut*: legs red.

DESCRIPTION.

This is met with in Silefia; builds in high trees, and feeds on fish, infects, &c.

PLACE.

RED-LEGGED H.

SIZE of the Green Heron. Neck short: bill blue and green, with a black tip: irides yellow, incircled with red: head crested; the colour yellow and black: throat, neck, and whole body, saffron-colour, inclining to chesnut, palest above: tail very short: legs of a deep red, like those of a Pigeon: claws black.

DESCRIPTION.

Inhabits Italy, chiefly about Bologna.

PLACE.

This colour should more properly be termed rufous, as Schwenefield, who first mentioned it, calls it ardea rubra.—Hist. des Ois.

38. Var. A. Le Crabier roux tacheté, Bris. Orn. v. p. 471.

DESCRIPTION.

IKE the last, except the neck, which is spotted with black on the sides; and the legs yellowish instead of red.

This is a mere variety of the last, if not a young bird.

squacco H.

Ardea comata, Pall. Trav. iii. p. 715. No 31.

Le Guacco, Buf. Ois. vii. p. 392.

Crabier de Mahon, Ibid. p. 393.—Pl. Enl. 348.

Sguacco, Raii Syn. p. 99. 8.—Will. Orn. p. 381. 8.

Lev. Mus.

DESCRIPTION.

SIZE of the blue Heron. Bill of a livid red, with a brown tip: lore greenish: irides yellow: crown of the head much crested, six of the feathers hanging quite down to the back; these are narrow, white margined with black: the neck and breast pale ferruginous; the feathers on the first very long and loose: back ferruginous, inclining to violet, and furnished with long narrow feathers, which reach beyond the wings when closed, and fall over them: wings, rump, tail, belly, and vent, white; the tail pretty long: legs stout, of a greenish yellow; claw of the middle toe serrated within.

PLACE.

This is an elegant species, and inhabits the bays of the Caspian Sea, and the flow streams of the southern Desert. It is also met with in Italy, about Bologna, where it is called Squacco, and is said to be a bold and courageous bird.

Le Crabier de la Cote de Coromandel, Buf. Oif. vii. p. 393.-Pl. Enl. 910.

ENGTH twenty-one inches. The bill is yellow: between the bill and eyes bare and grey: the head not crefted: general colour of the plumage white: the upper part of the head, and hind part of the neck, inclining to rufous; as are the long feathers which hang over the breaft; there is also a rusous tinge on the back and wing coverts: the legs are yellow.

DESCRIPTION.

Inhabits the coast of Coromandel. It seems to be a variety of the last, if not differing in sex.

PLACE.

In the Br. Mus. is one answering in most respects to this, except in having a crest composed of several long feathers, striped dusky and white, and reaching to the middle of the neck: the feathers of the lower part of the back are narrow and long, and reach beyond the tail: legs brown. I judge this to be a variety of the male of the above-described.

Ardea castanea, N. C. Petr. xv. p. 454. 9. t. 15. (Gmelin.) Ardea ralloides, Scop. Ann. i. Nº 121.

DESCRIPTION.

LENGTH one foot ten inches and a half. Bill near three inches long, black, the base of it livid: between the bill and eye green: irides faffron-colour: creft reaching to the middle of the neck: throat white: fides of the head yellowish; neck the fame, inclining to chefnut: back rufous-chefnut, covered with long narrow feathers: breaft, belly, wings, rump, thighs, and tail, white, tinged with yellow in some parts: the inner webs of some of the quills have a few spots of black, and the tips L 2

PLACE.

tips of the tail feathers are also marked with black: legs saffron-colour: claws black, and much bent, except the hinder one.

This bird inhabits Russia, about the River Don, coming thereto from the Black Sea, and Arabia*; but does not stray far inland. It builds in trees. It seems a mere variety of the Sguacco, if not differing in sex. Scopoli observes, that at a certain time of the year it emits an agreeable smell.

FERRUGINOUS
H.
DESCRIPTION.

Ardea ferruginea, N. C. Petr. xv. p. 456. t. 16.

LENGTH twenty-one inches and a half. Bill strait, sharp; the base greenish slessh-colour, the end brownish; the upper mandible somewhat bent at the tip: between that and the eyes, and over them, naked and green: irides saffron-colour: feathers of the head, neck, and back, longish, black tipped with ferruginous; those on the crown somewhat elongated: chin yellowish white: wing coverts black brown; the outer ones have ferruginous tips; those nearest the body varied with rusous and white: quills black: rump, breast, and belly variegated with ferruginous, whitish, einereous, and brown; thighs, with rusous and cinereous white: the wings, when closed, reach a triste beyond the tail: legs green.

PLACE.

This species is found about the river Don, in the summer only; as it is migratory, coming from the Black Sea, and departing to it again in autumn. Feeds on fish and insects. Frequently met with along with the last species.

. Dec. Ruff. i. 164.

Ardea

Ardea pumila, N. C. Petr. xiv. p. 502. pl. 14. 1.

DWARF H.
DESCRIPTION.

ENGTH nineteen inches and a half. Bill three inches, black, with yellow edges; the lower mandible yellowish white, with a dusky base: lore and irides yellow: head, hind part of the neck, and sides, white; sometimes rusous white, with dull chesnut margins and white tips: throat white; from it a longitudinal stripe of the same colour passes down the fore part of the neck to the breast, which with the belly is yellowish white: the scapulars, lesser wing coverts, and back, are chesnut; the other coverts mixed white and pale yellow: the two first quills are ash-colour on the outer webs, the rest only at the tips, obscurely shaded with rusous and white: rump and tail white: legs dusky: claws blackish.

Inhabits the borders of the Caspian Sea.

PLACE.

Br. Mus.

CINNAMON H.

DESCRIPTION.

SIZE of the Green Heron: length to rump * one foot. Bill two inches and a half long, and yellow: general colour of the plumage cinnamon-colour, verging to chefnut, much paler on the under parts: chin and vent almost white: down the middle of the fore part of the neck streaked with brown: on each side of the throat, under the jaw, a small patch of white: legs yellow.

Inhabits China.

f. 3.—Brown Jam. p. 478.

Blue Heron, Catefo. Car. pl. 76.—Art. Zool. N° 351.

Lev. Muf.

DESCRIPTION.

SIZE rather less than a Crow: weight fifteen ounces: length near eighteen inches. Bill three inches; colour blue, yellowish beneath: irides yellow: round the eye, and between that and the bill, bare and yellowish: the head feathers are somewhat crested, and those of the breast elongated: the general colour of the plumage deep blue, inclining to lead-colour: head and neck changeable purple; the back covered with narrow, long, silky feathers, hanging near four inches beyond the tail: legs green.

FEMALE.

The female has the head and neck of a dull purple: chin white, passing in a streak half-way down the neck before; the lower part mixed white and black in streaks: the head is scarcely crested: the back lead-coloured; and the long silky feathers of it, so conspicuous in the male, wholly wanting.

Inhabits

Inhabits America. Found in Carolina in spring: in winter inhabits Jamaica, and other islands of the West Indies. It has also been met with at Otabeite, and other islands of the South Seas, where it is much respected*.

PLACE.

Le Crabier bleu à Cou brun, Buf. Ois. vii. p. 399: Heron bleuatre de Cayenne, Pl. Enl. 349.

VAR. A.

DESCRIPTION.

THE length of this bird is nineteen inches. The bill is deep yellow: between the bill and eye bare and reddish: head and neck rusous brown: at the hind head spring two long feathers, which reach almost two-thirds down the neck: the rest of the body, wings, and tail, deep blue: legs brown.

This inhabits Cayenne.

PLACE.

SIZE of the last: length eighteen inches. Bill two inches and a half; colour yellow: the bare skin between that and the eye the same: the irides also pale yellow: the head feathers loose, and somewhat elongated at the back part: general colour of the plumage pale blue green: chin and throat white: legs yellow: claws black.

VAR. B. Description.

Inhabits Queen Charlotte's Sound, where the natives call it Ma-took.

PLACE.

^{* &}quot;So far are the Otabeitans from eating all kinds of birds, that they have "a kind of superstitious regard for Herons and Kingfishers, almost like that "which is paid to the Stork, the Robin-red-breast, Swallow, and other harmless familiar birds in England."—Forst. Obs. p. 207.—Parkinson talks of a grey Heron being sacred at Ethooa, p. 70.

VAR. C.

DESCRIPTION.

HIS is fcarce as big as a Pigeon: length fixteen inches. The bill two inches and a half long, dusky, the under part white: irides, and bare skin round the eyes, yellow: the general colour of the plumage is black, with a polished steel gloss, mixed with a little brown on the head, and brown and yellowish on the back, with the addition of ash-colour on the wing coverts: all the under parts are white, variegated with cinereous and pale yellow seathers: the quills are greenish, with a white spot near the tips: the tail the same, but not marked with white: legs yellow.

PLACE.

This inhabits *Brafil*, and is a flately species, walking erect: it is by the natives called *Cocoi*.

46. YELL**O**W-CROWNED H. Description.

ENGTH fifteen inches and a half: weight half a pound. The bill near two inches and three quarters long, and black: irides red; the bare skin round them green: crown of the head yellow, ending in a crest, which elongates into sour or five white feathers, the longest near six inches; the rest of the head is blue black; on each side is a white streak from the corner of the mouth.

mouth, tending towards the hind head: the back streaked black and white; and from the lower part are long narrow feathers, which hang over the tail, as in many of the *Heron* genus: the whole of the under parts, from the chin to the vent, is of a dusky blue: the quills are blueish brown: tail dull blue: legs yellow: claws dusky.

This species is found in *Carolina*, in the rainy season; but at the *Bahama Islands* they breed among the rocks, in the bushes on the banks: at this last place they are called *Crab-catchers*; and are in so great plenty, that one may load a boat with theyoung ones in a few hours; being so far from shy, that they will scarce get out of the way of those who mean to take them. They are accounted pretty good eating.

HIS is a beautiful though common species.

Description.

The Male weighs about three pounds and a half: length three feet three inches. Bill fix inches long, colour dusky, beneath at the base yellowish: round the eye greenish, and bare of feathers; irides yellow: forehead and crown white; sides of it over the eye black: all the feathers of the crown long, two in particular being eight inches in length; on the whole forming a most elegant crest*: the neck white; the fore part of it marked with a double row of black spots: wing coverts blueish grey: outer edges of the wing white: bastard wing, and greater quills, black: middle of the back almost bare, covered by the scapulars, which are grey and white, of a loose texture, long and narrow:

* These are used as ornaments in the East, and bear a considerable price. We believe that this appendage is found only in males of a full age, or perhaps very old birds.

the feathers of the lower part of the neck before are also of the fame texture, and hang loose over the breast: on each side, under the wing, a bed of black feathers: breast and under parts white: legs dirty green: inner edge of the middle claw ferrated.

FEMALE.

The Female has little or no crest: the head grey: feathers over the breast short: scapulars of not so loose a texture as in the Male; but in other things much resembles that sex.

PLACE AND MANNERS. This species is very common in these kingdoms; and frequently sound, except in breeding-time, dispersed throughout the marshy places, and edges of streams, where it may be seen motionless for hours together, waiting the passing of a fish*, which it may snap up for food; in this interval the head is crouched between the shoulders, and the body frequently resting on one leg. Besides fish, it will eat frogs, and at times seed on vegetables. In slying it draws in the head between the shoulders, the legs hanging down. In breeding-time unite together in large societies, and build in the highest trees; making a nest of sticks, lined with a sew rushes and wool, or feathers. The eggs are pale greenish blue, sour or five in number. It may be brought up tame, if taken young, but when old birds are captured, they shortly pine away, and will resuse nourishment. Sometimes make the nest in high clisss over the sea.

Heron-bawking was formerly a favourite diversion, and a pe-

^{*} They are great destroyers of fish. We remember to have seen a fish of ten inches long, taken out of the stomach of one. Others are mentioned to have seventeen Carps at once found within them; and a tame one has been known to eat fifty small Roaches and Dace, one day with another.—Gent. Recreat. Svo. p. 32.

[†] So many as eighty in one tree.—Br. Zool.

nalty of twenty shillings incurred on taking the eggs; but now out of esteem, as is in a great measure their slesh, though rated at a great price in former times, equal to that of a Peacock*.

There is scarce a place, either in the old world or in the new, where this bird has not been met with: witness the relations of numberless voyagers; yet few talk of its migrations. Indeed M. Ekmarck + mentions the disappearing of the whole of the Heron tribe from Sweden, in autumn: and this species is said only to be feen in New York from May till October 1.

Ardea Herodias, Lin. Syft. i. p. 237. 15. - Scop. Ann. i. No 118. Le Heron hupé de Virginie, Bris. Orn. v. p. 416. 10. Le grand Heron d'Amerique, Buf. Ois. vii. p. 385. Largest crested Heron, Catefo. Car. App. pl. 10. fig. 1. - Art. Zool. No 341.

DESCRIPTION.

THIS is a very large species: length more than five feet. Bill full eight inches long; colour of it brown, inclining to yellow on the fides: the head is crefted; fome of the feathers which compose it are five inches in length: between the bill and eye bare, of a pale yellow: the neck and breast are rusous; the fore part of them fpotted with brown: all the upper parts of the body, belly, tail, and legs, brown: quills black §.

ASH-COLOUR-ED H. Description.

ENGTH two feet one inch. Bill ftrong, black: cheeks and chin whitish: neck pale cinereous brown, streaked before with white: back, wings, and tail, cinereous, clouded round each feather with dusky: feathers on the sides of the back long and broad, hanging over the ends of the wings: belly white: legs yellowish.

PLACE.

Inhabits New York: arrives in May; breeds, and leaves the country in October.

Streaked Heron, Art. Zool. No. 354. Lev. Mus.

STREAKED H.

ENGTH feventeen inches. Bill two inches: crown dusky: cheeks and hind part of the neck rusty and black: chin, throat.

DESCRIPTION.

throat, and fore part of the neck, white; the last streaked with black; wing coverts streaked black and pale buff-colour: outer edge of the wing white: quills dusky: legs greenish.

Another of these, supposed to differ in sex, has a white line on each jaw: scapulars and greater wing coverts dusky, spotted with white at the ends.

PLACE.

Inhabits North America.

56. REDDISH EGRET. L'Aigrette rousse, Buf. Oif. vii. p. 378.—Pl. Enl. 902.—Ara. Zobl. No 348.

DESCRIPTION.

ENGTH two feet. Bill yellowish, with a dusky point: lore and round the eye green: the head and neck are covered with loose long feathers of a rusty rusous colour: the long narrow feathers of the back of the same colour: the rest of the body blackish grey: legs black.

PLACE.

Inhabits Louisiana.

DEMI EGRET.

La Demi-Aigrette, Euf. Ois. vii. p. 378. Heron bleuatre à ventre blanc de Cayenne, Pl. Enl. 350.

DESCRIPTION.

ENGTH scarcely two feet. Bill dusky yellow; between that and the eye bare, and of the same colour: the head and neck, as far as the breast, and the upper parts, wings, and tail, are deep blue black: the under parts of the body, and thighs, white: the legs yellowish: at the hind head hang two long feathers, of the same colour with the head: and on the lower part of the back are a few long narrow rusous feathers, which fall over the tail, which is very short.

Inhabits

Inhabits Cayenne. I met with one of these in a collection from that part: it was two seet in length: bill yellow; tip black: crest long, and white: head and neck inclining to violet: chin and throat mottled with rusous white: long seathers over the rump grey: legs brown: in other things it answered to the above description.

PLACE.

La grande Aigrette, Buf. Ois. vii. p. 377.—Pl. En!. 925.—Artt. Zool. N° 346.

58. GREAT EGRET.

Guiratinga, Raii Syn. p. 101. 17?-Will. Orn. p. 285?

THIS is double the fize of the European Egret, and the head is not crefted as in that species. The bill is of a dirty yellow; with the top and end dusky: the whole plumage white: the narrow feathers which spring from the back are much longer in this bird, and fuller, so as to hang beyond the tail: the legs are black.

DESCRIPTION.

This is found at Cayenne, Guiana, and other parts of South America; also at St. Domingo and Louisiane: at the first-named place is frequent, among the islets in the wet savannas; not on the borders of salt-water rivers, nor the sea; but only near stagnant waters or rivers, where it can shelter itself among the reeds. They do not collect in slocks, and are very shy, though not uncommon. Bougainville * also met with Egrets in Falkland Islands, and took them at first for common Herons. Towards night they made a harsh barking noise, not unlike that of the wolf which frequents those parts.

yellow:

yellow: crown of the head blueish ash-colour: the nape and hind part of the neck brown, mixed with fillemot: the back and rump, like the crown, mixed with dull green and rusous: the under parts are white, spotted with fillemot as far as the breast; from thence to the vent ash-colour: the lesser wing coverts are dull green, with rusous edges; the greater and quills black, edged with white: the tail greenish black: legs yellow: claws black.

This species is found in *Chili*, and other parts of *America*, on the banks of rivers at a distance from the sea. It is called by some *Cra-cra*, from its cry, which it exhibits in its slight. The natives call it *Jaboutra*. It is met with also at *Martinico*.

PLACE.

Heron de la Côte de Coromandel, Pl. Enl. 906. Le Heron violet, Buf. Oif. vii. p. 370.

69. VIOLET H.

THIS is thirty-three inches in length. The bill is dusky brown: the top of the head, the lower part of the neck, the body, wings, and tail, of a blueish black, glossed with violet; the rest of the head and neck white: the vent and under tail coverts the same: legs reddish brown.

DESCRIPTION.

Inhabits the Coromandel coast.

PLACE.

Le Héron Agami, Buf. Ois. vii. p. 382 .- Pl. Enl. 859.

AGAMI H.

LENGTH thirty-one inches. Bill long, dusky: the crown of the head blue black: the nape a light blue; from this hang fix or eight long narrow feathers, the largest almost the whole length of the neck: back, wings, and tail, deep blue: the neck and under parts of the body rusous; but the lower half of Vol. III.

DESCRIPTION.

the neck and the fides of it are covered with loofe blue feathers, hanging longer and loofe on the breaft: from the lower part of the back are long flender feathers, which hang loofe, and reach the end of the tail: on the fides of the head, and just above the eye, the parts are white, passing a little way in a line on each fide of the neck: legs yellow.

PLACE.

This is a most beautiful species, and inhabits Cayenne. One of these, which I suppose to be a female, is in the collection of Colonel Davies. The bill is five inches and three quarters long, and blackish; the base of the under mandible pale: the crown, crest, and hind part of the neck, blueish ash-colour: chin white: sides of the neck, as far as the middle, fine rusous; down the middle of this a beautiful white and rusous line, bounded on each side with black: the breast covered with long, loose, black-ish feathers: those on the back part of the neck black, but streaked down the middle of the shaft with white: the upper parts of the body, wings, and tail, sine green, like that of a Duck's head, and glossy; the under parts deep rusous: quills black: tail brown. I have never seen the male; but by Busson's description it must be still more beautiful than the female, and is certainly the most elegant of the genus.

Cocol H.

Ardea Cocoi, Lin. Syst. i. p. 237. 14. Le Heron hupé de Cayenne, Bris. Orn. v. p. 400. 3. Le Soco, Bus. Ois. vii. p. 379. Cocoi, Raii Syn. p. 100. 15.—Will. Orn. p. 284. pl. 51. Blue Heron, Albin. iii. pl. 79?

DESCRIPTION.

THIS is a large species, in length above three seet. The bill of a greenish yellow: irides of a gold-colour; top of the head

head cinereous; the fides of the upper part black; the feathers of the hind head are cinereous, very long and narrow, forming a handsome crest, being about five inches and a half in length *: between the bill and eye bare and cinereous: cheeks, throat, and neck, white; the fore part of the last marked with a double row of longish dusky spots; the feathers of the lower part very long, and hang over the breast: the rest of the bird fine pale ash-colour: on the back the feathers are long and narrow, and hang down behind, like many of this genus: the legs are ash-colour.

Inhabits Brasil and Cayenne. Said to be pretty good eating in the rainy feason, at which time it is fat.

PLACE.

Ardea rufa, Scop. Ann. i. Nº 119 .- Kram. El. p. 347. Nº 6.

72. RUFOUS H.

LESS than the common Heron. Bill seven inches long: from the eye to the nape on each fide a black ftreak: head, neck, belly, quills, and tail, black: breast rusous: temples and thighs ferruginous: lower part of the neck whitish, marked with longitudinal brownish spots: the upper part of the neck, the back, and wings, cinereous brown: legs brown.

DESCRIPTION.

Inhabits the Austrian dominions.

PLACE.

SIZE fmall. Bill long, pale yellow: upper part of the plumage brown, dashed with a paler brown; under parts the fame, but more dilute: quills and tail black: legs green.

Description.

Inhabits China, and called Soy-ie. The description taken from a collection of Chinese drawings.

DESCRIPTION.

I ENGTH two feet three inches. Bill feven inches, black: the fore part of the head is variegated with white and black, the rest of the head purple; at the back part a crest of the same colour: the general colour of the bird cinereous: edges of the wings white: wing coverts blue and ash-colour, mixed: the fecond quills nearly of equal length with the prime ones: legs variegated with brown, black, and yellowish.

Inhabits the wet places of Mexico, but is scarce, being only

feen at intervals. Buffon gives it the name Houbon, from its supposed cry being PLACE.

Le Bec ouvert, Buf. Ois. vii. p. 409.-Pl. Enl. 932.

PONDICHERRY

THIS is a fingular species, and measures in length sourteen inches and a half. The bill is as long as in the Heron tribe, very thick and flout at the base, for about one sourth of its length, it then becomes slender, and finishes in a point; the under mandible is less stout, and gradually lessens to the end, but is curved inward the whole length, fo that the mandibles only touch at the bases and tips, standing hollow from each other in the middle; the colour of both is yellow, but towards the head dufky: the

DESCRIPTION.

* The same name is also given by Buffon to a Cuckow. See Ægyptian Cuckow, vol. i. p. 522. No 16. of this work.

fpace

space between the bill and eye, and round the last, is quite covered with feathers: the general colour of the bird is a dirty, cinereous grey; but the quills are black, and greatly exceed the tail in length: the legs are yellowish, and tessellated their whole length, as is the bare part of the thighs: the claws are small and black, the middle claw not ferrated.

PLACE.

Inhabits Pondicherry, and other parts of the East Indies.

78.
COROMANDEL
H.
Description.

Le Bec-ouvert des Indes, Son. Voy. Ind. vol. ii. p. 219. pl. 219.

DIFFERS from the last, in that the edge of the upper mandible is serrated from the middle to the end, the toes united at the base to the first joint, and the wings reach only to the tail: the head, rump, belly, and wing coverts, are white; those of the head are short, narrow, and erect: the back, quills, and tail, black: from the base of the bill to the eye, bare and black; this black bare space also extends round the throat: the bill is rusous yellow: irides red: legs rusous yellow.

PLACE.

Found on the coast of Coromandel, in September, Ostober, and November. Frequents, like the Heron, the borders of rivers and ponds, for the sake of fish and reptiles, which are its food.

SCOLOPACE-OUS H. Description. Le Courlan, ou Courliri, Buf. Ois. vii. p. 442.—Pl. Enl. 848.

THIS is a large bird, almost equalling an Heron in size: the length twenty-five inches. Bill four inches long, reddish with a blueish point; it is rather stout at the base, and nearly strait, but inclines downward towards the tip: on the upper mandible is a long surrow two thirds of the length of the bill, in which the nostrils are placed, these seem to be a slit only: round

round the eye bare * of feathers, and of a reddish brown colour: the plumage in general is brown, glossed with a reddish copper-colour on the quills and tail: most of the feathers of the upper part have the edges paler than the rest of the feathers; and those of the neck and breast are streaked with white down the shaft: the chin white: the naked parts of the thighs and legs are white: the toes are not joined by a membrane at the base, but the middle claw is pectinated on the inner margin, where it rises into an edge.

This inhabits Cayenne, and is a doubtful species, hanging between the Heron and Curlew, but seems most allied to the former.

PLACE.

• Not clear, it feems to be so in the Pl. Enl.

Wood Pelican, Catesb. Car. i. pl. 81.—Ara. Zool. Nº 360.

DESCRIPTION:

SIZE of a Goofe: length three feet. The bill is flout, nine inches in length, and bends downwards towards the tip; the colour of it yellowish brown: irides pale rusous: the fore part

of the head, and round the eyes, covered with a blue skin: from the head to the middle of the neck the skin is also bare of feathers, but rough and warty, and of a brown or blackish colour: beneath the jaw is a pouch holding at least half a pint: the whole plumage of the bird is white, except the quills and tail, which are black: the bare part of the thighs is four inches, the legs above a foot long, the colour of both dusky: between the toes a membrane.

The male and female are much alike.

Birds of this species are sound in Carolina, and in various parts of South America, where they frequent the open savannas, which are under water during the summer; but retire from the first in November. They often sit on the tall Cypress-trees in numbers together, resting their ponderous bills on their breasts: are stupid birds, and easily shot when once met with. They seed on fish and reptiles, but are accounted pretty good eating. Are known at Brasil by the name of Curicaca, and are called by the Portuguese, Masarino.

In the Museum of the late Dr. W. Hunter is a fine specimen, which came from Cayenne. The bird referred to in Dampier was met with at Sharks Bay, New Holland.

Scarlet Ibis, Ara. Zool. No 361.

Br. Muf. Lev. Mus.

DESCRIPTION.

ENGTH twenty-one inches. Bill between fix and feven inches long, and of a pale red: eyes black: the base of the bill passes a little way back on the forehead: the sides of the head, quite beyond the eyes, are bare, and of a pale red: the whole plumage is of a glowing scarlet, except four of the outer prime quills, which are of a glossy blue black at the ends: the shafts of the quills and tail are white: legs pale red.

FEMALE.
PLACE AND
MANNERS.

The female differs in the colours being somewhat less lively.

This beautiful species is met with in most parts of America within the tropics; also pretty common in East Florida, and a sew are seen in the south of Carolina; in some of the West India islands in great plenty, especially the Bahamas. It generally frequents the borders of the sea, and sides of the neighbouring rivers, and lives on small fry of sish, and insects, which it picks up when the sea retires from the shore. These birds frequently perch on the trees in great numbers, but lay their eggs on the ground *, on a bed of leaves; the eggs are of a greenish colour: the young,

when

[•] Pernetty fays that the female lays her eggs on the house-tops, and the holes of walls.—Voy. i. p. 183.

when hatched, are black, in a little time after grey, but are nearly white before they are able to fly; from this they change to red by degrees †, but it is not till the third year that the red colour is complete, and in many birds even at that time many of the neck feathers are found mixed with brown. It is mostly seen in numbers together, and the young birds and old ones keep in separate flocks: is frequently domesticated, in the parts where it naturally inhabits, and I have also known it brought to England for the same purpose. I have one now by me, which lived for some time among the poultry; but it grew sickly, lost all the brilliancy of plumage, and before it died faded to a dull rose-colour. By some it is esteemed for food.

Le Courlis des Bois, Buf. Oif. viii. p. 42.

verd de Cayenne, Pl. Enl. 820.

CAYENNE L

RATHER less than the last: length twenty-two inches. The bill bent, five inches and a half long, and dusky; the base, and round the eye, bare, and of a dusky pale red: the general colour of the plumage is black, with a greenish gloss in some lights; the quills and tail deepest: legs brownish yellow.

In some birds the top of the head and nape have the middle of each feather dashed with deep black, without any reslection of green, and the legs almost black; at first sight this may be taken for the young bird of the Scarlet Ibis; but in the one here

† Ulloa is faid to have met with large flights of Curlews within twenty or thirty leagues of Juan Fernandez; these were mostly white, except the breast and upper part of the wings, which were of a rose-colour.—See Voy. ii. p. 228. Most likely they were this species.

DESCRIPTION.

described.

described, the legs are only eight inches in length, whereas in the Scarlet Ibis they are twelve at least; in the first they do not reach to the end of the tail, but in the last much beyond it.

PLACE AND MANNERS.

This is met with at Cayenne, but not in numbers; always in pairs: perches on the decayed trees which float down with the stream, in order to fish, generally at some distance from the sea: and is called by the people at Cayenne, Flammant des Bois.

MEXICAN I.

Le Courly varié du Mexique, Bris. Orn. v. p. 333-7. L'Acalot, Bus. Ois. viii. p. 45. Acacalotl, Raii Syn. p. 104. 5. Acacalotl, or Water Raven, Will. Orn. p. 296.

DESCRIPTION.

THIS is a large species, being three feet in length. The bill eight inches, and blueish: irides red: between the bill and eyes, and round them, bare and reddish: the head and neck covered with dusky, white, and green feathers, with a few yellow ones intermixed: back and rump black, glossed with green and purple: breast and belly brown, with a little mixture of red: the wing coverts are green; and the quills and tail green bronzed with copper: legs black.

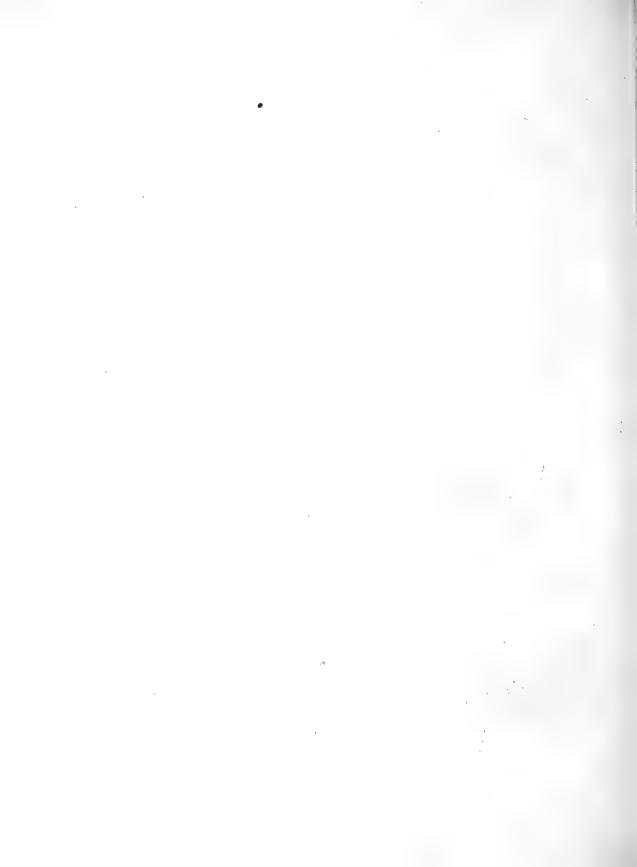

PLACE.

This inhabits *Mexico*, frequenting the lakes, and feeding on fish: it breeds in those places, and is accounted pretty good food.

BLACK-FACED
I.
PL. LXXIX.
Description.

SIZE large, not much inferior to the Wood Ibis: length twenty-eight inches, breadth forty-nine inches and a half. Bill fix inches, and black: tongue triangular, ciliated at the back part: irides reddifh: the whole face, quite beyond the eyes, is bare of feathers.

feathers, black, and warty, particularly round the eyelids: under the chin hangs a loofe, wrinkled, bare skin, forming a pouch: the crown of the head is deep sulvous yellow, and the feathers at the back part longish: the rest of the neck and breast pale yellow: the back and scapulars are cinereous, margined with brown: across the breast a band of the same: the middle of the feathers of the back brown: the wing coverts blueish ash-colour, margined with brown: the quills, sides, thighs, vent, and tail, are greenish black; the last consists of twelve feathers, and is rounded in shape: the legs seven inches long, rough, naked but a little way above the knee, and red: claws black.

This species was found by Dr. Forster on New Year's Island, near Staten Land*. It builds the nest in inaccessible places in the rocks. The specimen is in the collection of Sir Jos. Banks.

PLACE.

Emfeefy, or Ox bird, Shaw's Traw. p. 255.

HIS is a large bird, formewhat exceeding the Stork, and measures from thirty to forty inches in length. The bill is seven inches long; the colour yellow, growing reddish towards the tip; it is slightly curved, and ends in a blunt point: the fore part of the head, all round as far as the eyes, is naked and reddish: the skin under the throat is also bare and dilatable: the plumage

Description.

plumage reddish white, most inclining to red on the back and wings: quills and tail black: the legs are long, and the thighs bare for three parts of their length; the colour of them red: the toes united as far as the first joint. Hasselquist adds, that the irides are whitish, and the end of the bill, and the legs, black: and that it is found in Lower Egypt in great plenty, in places just freed from the inundations of the Nile. It lives on frogs and infects: feen in gardens, morning and evening, and fometimes in fo great plenty, that whole palm-trees are covered with them: when at rest they sit quite erect, their tail touching the legs. This author believes it to be the *Ibis* recorded by the antients; first, because it is both common as well as peculiar to Egypt: fecondly, as it eats ferpents as well as other things: and thirdly, because the urns, which contain the remains of embalmed birds, found in the sepulchres along with the mummies, seem to contain fuch as are of this fize.

I suspect it to be the *Emseesy* or Ox Bird of Shaw. He describes it as wholly white, except the bill and legs, which are of a fine red: and says it feeds in the meadows, with cattle: but the flesh is unsavoury, and soon corrupts.

BLACK I.

Lev. Muf.

CIZE of our Curlew: length one foot nine inches. Bill near DESCRIPTION. four inches long, and brown: from the bill, all round the eye, bare, and dufky green: the head and neck are chefnut, verging to brown on the head, where the feathers have pale edges: the upper parts of the body are gloffy green, appearing bronzed in different lights: the breaft, belly, and under parts, are brown, with a gloss of green gold on the breast: quills and tail darker than the back, and with very little gloss: legs dusky blue: between each toe a small membrane at the base.

VOL. III.

This

12. BAY I.

^{*} Circa Pelusium tantum nigra est, cæteris omnibus locis candida.—Plin.

[†] Instanced in the Egret, Red Ibis, and many others.

114

PLACE.

This inhabits *Italy*, fome parts of *Germany*, and is also very common about the *Caspian* and *Black Seas*, ascending up the rivers to breed. Frequent in flocks about the lakes; but none seen in *Sibiria*, though faid to be met with in *Denmark**, where it is called *Ryle-Domsneppe*.

VAR. A.

Le Courly marron, Bris. Orn. v. p. 329. 5.

DESCRIPTION.

HE plumage in this is mostly of a glossy chesnut, and the breast has a green tinge. It is most likely a variety of the last described, and sound on the shores of the Danube.

GREEN I.

Description.

Numenius viridis, N. C. Petr. xv. p. 462. t. 19. (Gmelin.)

SIZE of the Curlew: length nineteen inches and a half. Bill three inches and a half; much bent, smooth, and of a lead-coloured brown; the lower mandible slessh-colour at the sides, and beneath: irides pale: between the bill and eyes black, rough, and naked: under the chin the skin is dilatable, forming a small pouch: above the eye a white spot, beginning behind, and tending to the hind head: on the crown two or three irregular spots of the same; excepting these spots the head is blackish, the feathers margined with a pale colour: chin blackish, marked with small whitish spots: neck greyish black; on the upper part before three transverse whitish bands, with a fourth beneath them, but less distinct: back and tail green gold: rump, breast, belly, and thighs, blackish brown: wing coverts and quills deep shining green, glossed with blue: legs and claws deep black.

* Muller. Brunnich.

This has the fame haunts as the next species, and feeds in the fame manner, being often found together; but differs in not soaring so high, rather skimming along the air, somewhat in the nature of the Swallow. It seems to have great affinity to the Bay Ibis.

PLACE AND MANNERS.

Numenius igneus, N. C. Petr. xv. p. 460. t. 18. (Gmelin).

Lev. Mus.

GLOSSY I.

ENGTH almost two feet. Bill five inches, smooth, roundish, much bent, green, fading to olive when dead: eye-lids brown: irides olive: eyes placed in a white space: under the chin a small dilatable pouch: head and neck black; the feathers fringed with white: the rest of the body variegated with blackish blue, green, and vinaceous, and in general very glossy; hence the bird, in slying, appears gilded when the sun shines upon it: quills green gold, and when closed reach the end of the tail: wing coverts next the body reddish and blue mixed; the next series black, red, and green; the last, and quills, green gold: tail the same, glossed in different lights with red and violet: legs very long, of a bright green: claws crooked, black.

DESCRIPTION.

This inhabits Russia, chiefly the shores of the Don, and about the Choper: lives on fish and insects: slies in slocks, and builds on trees. In the Leverian Museum is one of these, which was shot in Cornwall.

PLACE.

WHITE-HEAD-ED I. Tantalus leucocephalus, Zool. Ind. p. 20. t. 10. White-headed Ibis, Ind. Zool. p. 11. pl. 10.

DESCRIPTION.

ARGER than our Curlew. Bill yellow, very long, and thick at the base, and a little incurvated: nostrils very narrow, and placed near the head: all the fore part of the head, quite behind the eyes, covered with a bare yellow skin, which seems a continuation of the bill; the rest of the head, neck, back, belly, and secondaries, white: across the breast a transverse broad band of black: the quills and wing coverts black: tail coverts very long, and of a fine pink-colour; these fall over, and conceal the tail: the legs and thighs very long, and of a dull sless-colour: the feet connected by webs as far as the first joint.

PLACE AND
MANNERS.

This bird was taken in the *Isle of Ceylon*, and kept tame for fome time at *Colombo:* it made a snapping noise with the bill, like a *Stork*; and, what was remarkable, its fine rosy feathers lost their colour during the rainy season.

ъб. BALD I. Courly à tête nue, Buf. Oif. viii. p. 32.—Pl. Enl. 867.

Br. Muf. Lev. Muf.

DESCRIPTION.

SIZE of the common Curlew: length from twenty-fix to thirty-one inches. Bill five inches and three quarters long, and of a red colour: the head and part of the neck bare of feathers, and tuberculated at the back part; the whole crown is red, the rest white: skin of the throat flaccid, dilatable, and bare of feathers: irides brown: the plumage in general black, glossed with green on the wing coverts; the tips of them glossed with coppen:

the

the tail confifts of twelve feathers, and is feven inches long: the wings reach almost to the end of it: legs pale red.

The female scarcely differs, except in having the top of the head more flat.

FEMALE.

Inhabits the Cape of Good Hope, and other parts of Africa. Found near watery places. Not difficult to be tamed, as one was kept for a time in the Company's garden at the Cape.

PLACE.

Le Courly brun de l'Isle de Luçon, Son. Voy. p. 85. pl. 47.—Buf. Ois. viii. p. 31.

MANILLA I.

SIZE of our Curlew. Bill greenish: eye encircled with a naked greenish skin: irides bright red: general colour of the plumage rusous brown: legs the colour of red lake.

Description.

Inhabits the island of Luçonia.

PLACE.

Br. Mus. Lev. Mus.

THE common length of this bird is two feet, but it is apt to vary much in fize. Bill feven inches, brown, near the end black; base of the under mandible sless-colour: the feathers of the head, neck, and wing coverts, pale brown, dashed down the middle with black: round the eye, on the fore part, white: back white, streaked with black: breast and belly white, marked with narrow longish lines of black: quills black, spotted on the inner

+ COMMON C.

DESCRIPTIONS.

inner webs with white: tail reddish white, barred with black: legs dusky blue.

Male and female much alike.

PLACE AND MANNERS.

This species is pretty common in England, where it is to be met with at all feafons: in the winter haunting the fea coafts and fens; repairing in summer to the mountains and more inland parts, to breed. The female in April lays four eggs, of a pale olive-colour, marked with brownish spots. The food, while in the neighbourhood of the fea, confifts of worms, marine, crustaceous, and other infects; at other times it feeds on flugs and worms, which it draws out of the earth morning and evening with its long bill. It is often met with in large flocks, and flies rather fwiftly. It is by many accounted good food, but is apt to have a rank taste *. It is also found in most parts of Europe; but in general retiring north to breed, and returning to the fouth as autumn approaches. Met with in Italy and Greece, and perhaps much farther to the fouth, as flocks are feen paffing over the island of Malta spring and autumn †. To the north it is found in plenty, in all the plains and open marshes, or heath grounds, of Russia and Sibiria; also in Kamtschatka, and in Europe as high as Lapmark and Iceland 1.

VARIETY.

DESCRIPTION.

THE Curlew is also found in America, but differs in some particulars; weighing from sourteen to eighteen ounces, and twenty inches in length. The bill is a trifle longer in proportion: the ground colour of the plumage pale rusous brown:

[•] I believe only when on the fea coasts; several which I have tasted, killed inland, were very good.

⁺ Hift. des Cif.

¹ Ar& Zool.

the crown of the head dusky black: the chin very pale: neck dashed with streaks of black: back and scapulars black; the feathers of the first margined, and of the last spotted on the edges with the ground colour: the wing coverts dashed down the shafts with black, ending in a point: the three first prime quills black; the sourch barred within; the rest, on both sides the shafts, with black; as are the rump, tail coverts, and tail: the under parts, from the breast, very pale reddish brown, or cream-colour: legs black.

I received a specimen of this from New York. Sir Asston Lever is likewise in possession of a second from Hudson's Bay, where it is seen on the coasts and marshes, the end of May: when the rivers are open, returns to the plains. It scrapes a few scattered leaves together by way of nest, on which it lays as far as three eggs, of a light blue spotted with black: the young hatched in July. They retire again to the marshes the middle of August; and leave the coast on the appearance of winter. Our last voyagers met with the Curlew at Hervey's Island in the South Seas*.

thighs,

thighs, and vent, white: breaft and fides yellowish, dashed with brown; the last barred transversely with the same: the three first quills are plain black; the fourth spotted on the inner web; and the others on both webs; the secondaries much the same, but the ground colour grey: tail grey, barred with brown: legs red brown.

PLACE.

This inhabits Madagascar, and seems very similar to our species.

LUZONIAN C.

Le Courlis tacheté de l'Isle de Luçon, Sonn. Voy. p. 85. pl. 48. -Buf. Dif. viii. p. 32.

DESCRIPTION.

HIS is much less than the common Curlew. The top of the head black; the rest of the head, neck, and breast, white, marked with narrow longitudinal streaks of black: the belly, with transverse semicircular bands of the same: wing coverts and back the colour of amber; on the margin of every feather from two to fix white spots: greater quills black: tail vinaceous grey, croffed with black lines.

PLACE.

Inhabits the island of Luconia.

Description.

TEARLY the fize of the common Curlew: length twenty inches. Bill four inches long, moderately bent, and brown; base reddish: the head and neck pale reddish white, marked with numerous dusky lines, perpendicularly placed: crown of the head brown: over the eye a pale streak: back dusky black, the feathers margined with pale reddish white, appearing waved: the under parts, from the breaft, of this last colour, with a few mottled

marks.

White-headed Curlow.

marks over the thighs: the wing coverts reddish white and dusky mixed: quills dusky, with pale edges: tail of a dirty yellow; the base half marked with irregular dusky spots; the end half barred across with the same: legs blue grey: claws black.

This inhabits Otaheite, where it is known by the name of Tevrea. In the collection of Sir Joseph Banks.

PLACE.

SIZE and shape of the common Curlew. Bill pretty long, and red: the head and part of the neck white: the rest of the plumage of a very deep blue, except the quills, which are black: legs cinereous grey.

ENGTH feventeen inches; breadth twenty-nine: weight fourteen ounces and a half. The bill three inches long, black; the base of the under mandible pale red: the head, neck, and breast, pale brown, streaked with dusky brown: chin white: the sides of the head are also somewhat paler than the rest; and between the bill and eye is a dusky streak: all the upper parts of the body and wing coverts are pale brown, streaked with dusky,

Description.

each feather being so marked down the shaft; besides which many of them are margined or marked on the edge with pale spots: the lower part of the back and rump are white: the upper tail coverts white, barred with dusky: tail brown, crossed with seven or eight darker bars: quills dusky black, marked on the inner webs with semicircular spots of dusky white; the shafts white: belly, thighs, and vent, dusky white: legs black. Such is the description of my specimen, which is the largest we have hitherto seen, the usual length being about sisteen inches; though Mr. Pennant mentions one which measured sixteen: in this the bill was only two inches. Hence it seems to vary in a great degree in respect to size.

PLACE AND MANNERS. The Whimbrel has much the fame manners as the Curlew, but is less common in England, and is migratory; at least passes from one part of the kingdom to another, according to the seafon. In the neighbourhood of Spalding, in Lincolnshire, it is met with in vast flocks, from April to May, on its passage to the north*, where it is said to breed. It is also seen in flocks about the same time on the Kentish coasts: and it may be that the major part pass elsewhere; yet many remain, as I had the satisfaction of receiving the one from which the above description was taken, from our intelligent friend Mr. Boys of Sandwich. This was shot at Romney in the month of August, where it is called a fack; with the assurance that many of them stay on those coasts throughout the summer, and breed thereabouts.

^{*} Breeds in the heath of the Highland hills, near Invercauld.—Flor. Scot. i. p. 32.—Tour in Scotl. 8vo. p. 108.—Br. Zool.

[†] It is probably called the Jack Curlew, from its being less in fize, though. like in colour, to the common Curlew; in the same manner as two of our Snipes are. distinguished.

This bird is also found in America; but seems to differ much in the same manner as the Curlew of that country does from the European one, being darker coloured.

BRASILIAN WH.

DESCRIPTION.

SIZE of the Whimbrel: length twenty-one inches. Bill four: colour brown, with a yellow base: the head and neck are brown; the feathers margined with whitish: the back, and under parts, from the breaft, of a chefnut brown: fcapulars, rump, upper and under tail coverts, and tail, bright brown, gloffed with green: wing coverts the same; but the greater ones, farthest from the body, are brown within: the quills are brown; the outer edges gloffy green brown: legs grey brown: claws blackish.

This is found at Brafil, Guiana, and other parts of South America.

PLACE.

Scolopax borealis, Eskimaux Curlew, Phil. Trans. vol. lxii. p. 411.—Ara. 8. + ESKIMAUX C. Zool. Nº 364?

Br. Mus. Lev. Mus.

A LITTLE more than half the fize of the Whimbrel: length thirteen inches; breadth twenty-one. Bill two inches long, bent, remarkably slender, and blackish; the under mandible rufous at the base: head pale, marked with longitudinal brown lines: forehead deep brown, with pale spots: neck, breast, belly, and vent, yellowish white; the two first dashed with brown flender.

DESCRIPTION &

slender lines: the feathered part of the thighs yellowish white, spotted with brown: sides under the wings rusous, transversely fasciated with brown: back deep brown, the feathers margined with greyish white: wings brown: shafts of the prime quills white: secondaries and lesser coverts margined with grey: lower coverts ferruginous, transversely fasciated with brown: rump brown, the feathers edged and spotted with whitish: tail short, brown, crossed with whitish bands: legs blueish black.

PLACE AND MANNERS.

Inhabits the fens of Hudson's Bay. Appears near Albany the beginning of May; going further north, and returning to Albany in August: it stays there till September, when it departs for the South. It lays four eggs, and appears in flocks, young and old together, till their departure. Found in flocks in Nova Scotia in Ottober and November. Feeds on the Black-berried Heath, and may be heard at a small distance, by a kind of whistling note.

Met with also in Newfoundland: called there Curlew. The natives of Hudson's Bay call it Wee-kee-me-nase-su. It is estemed for its delicacy of slavour. In the British Museum is one of these, which came from Rio Janeiro in South America.

This is certainly a distinct species.

CAPE C.

DESCRIPTION.

LENGTH fifteen inches. Bill three inches; the upper mandible hangs over the lower: noftrils placed at the base; from thence is a surrow the whole length of the bill: forehead cinereous: from the bill to the eyes a line of black: crown of the head, and the upper parts of the neck, back, and wing coverts, mixed and barred with ferruginous, black, and grey; crown of the head darkest: the under eyelid white: the chin pale ash-colour: fore part of the neck yellowish, marked with dusky minute dashes: the under parts of the body dusky white, barred with numerous dusky lines: quills dusky, marked on the outer web with triangular rusous spots, and the same on the inner web close to the shaft: tail rounded, tipped with ash-colour, and rusous on the outer web: legs pale slesh-coloured brown.

This bird inhabits England during the winter season, coming in with the Redwings: those which are with us during that time, supposed to come from Sweden, their appearance and disappearance from thence coinciding: about the beginning of October they are first seen, but continue coming till December: do not come in slights, but singly, or at most two together, and chiefly Vol. III.

DESCRIPTION.

PIACE AND MANNERS. of evenings, or very mifty weather: in general proceed inland immediately on their arrival; but should the wind be against them, and the passage over difficult, take a day's rest on the first land they make, and in this case have been met with so fatigued as to be taken by the hand. About the middle of March all tend towards the coasts for their departure; but if the wind be not favourable for their flight, multitudes are collected together, and the sportsman, availing himself of the circumstance, finds plenty of sport. Though Woodcocks in general leave this kingdom, yet a few are known every year to remain: Mr. Pennant mentions that a few breed in Case Wood near Tunbridge annually: a brace of them were shot in Chellenden Wood, by the gamekeeper to Horace Mann, esquire, May 1, 1769, and another brace the day before; they were fitting on their young. A friend of mine met with a female fitting on the eggs, and the male close at hand: she was so tame as to suffer him to stroke her without rifing; this was in a wood near Farningham, Kent: and about three years fince, in the fame wood, a brace of old birds, with five young ones in company, full fledged, were found; three of the young were taken, and given to a lady in the neighbourhood; one of them foon died, and is now in my possession: other instances also have been noticed by authors. They are stupid birds, and often taken in nets placed at the openings where they come out of the woods and return to them of evenings, which they do in particular paths; they are also caught in springes placed on the ground, or near it, fometimes by the legs, at other times by the neck; for, as these birds will not walk over the least obstacle which projects in their way, it is usual to place a range of stones, and in the avenues between to fet springes, by which means many are often

often taken. These birds are found also in the warmer parts of Europe, as well as Africa and Afia; in France, Italy, Greece, and Barbary; on the Gold Coast, and that of Guinea; as well as in China and Japan: in these places inhabit the plains in the winter, retiring in fummer to the fummit of the highest mountains to breed. To the north inhabit Sweden and Russia throughout, and Kamtschatka, as well as Iceland; hence a general inhabitant of the old continent, and its isles. Few need be told that its flesh is delicious, and much fought after; and, that nothing may be loft, the entrails are not drawn out, being thought a necesfary appendage as fauce to the bird.

It makes an artless kind of nest on the ground, composed of a few dried fibres and leaves, generally against an old stump, or great root of a tree: the eggs four or five in number, rather bigger than those of a Pigeon, of a rusous grey, marked with dusky blotches: the young run as foon as hatched, but, as they cannot immediately provide for themselves, the male and female accompany them for fome time.

We have observed three varieties: in the first, the head-of a pale red: body white: wings brown. The fecond, of a dun, or rather cream-colour: and the last, of a pure white. Specimens of which may be feen in the Leverian Museum, and in the collection of Mr. Tunstall.

VARIETIES.

Little Woodcock, Arct. Zool. p. 463. Lev. Mus.

LITTLE WOOD-

I ENGTH eleven inches and a half. Bill two inches and a Description. half long, the under mandible much the shortest: forehead cinereous: hind part black, with four transverse yellowish bars:

S 2 from from the bill to the eye a dufky line: chin white: under fide of the neck, breaft, belly, and thighs, of a dull yellow, paleft on the belly: hind part of the neck black, edged with yellowish red: back, and leffer coverts, the fame; the rest of the coverts marked with zigzags of black and dull red: primaries dufky: inner coverts rust-coloured: tail black, tipped with brown: legs short, pale brown.

PLACE AND
MANNERS.

This species is American, and appears in New York at the end of April, or beginning of May; when they lay eight or more eggs, in swampy woods: while the ben is sitting, the male of an evening often slies up perpendicular to a great height, and returns strait down to the same spot, and from the moment of its descent begins an agreeable kind of whistle, and continues it till it alights on the ground, and after staying a little time, repeats the same for several times together, and this sometimes even after it is dark. It lays the eggs on the ground, or some decayed stump of a tree, very close to it. Have been sound in Carolina in September. The slesh thought to be as excellent as that of the European species.

SAVANNA WOODCUCK. Description. La Becasse des Savanes, de Cayenne, Pl. Enl. 895 — Buf. Ois. vii. p. 481.

HIS is one fourth less than the common Woodcock, but has the bill longer in proportion; colour of it brown: over the eye is a black stripe, and between the bill and eye another: the upper parts of the plumage rusous, varied with black, somewhat in the manner of our Woodcock, but more distinct: the under parts are dusky white, and the black marks the same; but those from the breast to the vent are transverse blotches, not lines, as in the Woodcock. It seems a species between our great Snipe and Woodcock, but is most allied to the latter. The legs are brown.

This

This inhabits the moist favannas of Cayenne; in the rainy seafon moves into the highest situation to breed. It makes the nest on some rising ground, choosing a cavity, and lining it with dried leaves: lays two eggs; and makes two nests in a year, the last in July: does not fancy the woods, like that of Europe, but the marshes only, like the Snipe. PLACE AND MANNERS.

The flesh of these thought to be as good as the European species.

Scolopax media, Frisch. t. 228. Great Snipe, Br. Zool. ii. No 188.—Art. Zool. p. 470. B. Lev. Mus.

GREAT SNIPE.

SIZE between the Woodcock and Snipe: weight eight ounces: length fixteen inches. Bill four inches long, and like that of the Woodcock: crown of the head black, divided down the middle by a pale stripe: over and beneath each eye another of the same: the upper parts of the body very like the common Snipe: beneath white: the feathers edged with dusky black on the neck, breast, and sides; and those of the belly spotted with the same, but the middle of it is plain white: quills dusky: tail reddish, the two middle feathers plain, the others barred with black: legs black.

DESCRIPTION.

This is a rare species: a fine specimen of it has been shot in Lancashire, now in the Leverian Museum: faid also to have been met with in Kent. It is found likewise in Germany, and inhabits the Arctic region of Sibiria. I once saw this among a parcel of birds from Cayenne, and have no reason to suppose otherwise than that it came from that part.

DESCRIPTION.

three inches long, colour dusky; flat at the end, and rough: the head is divided by two black lines lengthwise, and three of red; one of the last passing down the middle of the head, and one above each eye: between the bill and eye is a dusky line: chin white: neck varied with brown and red: the scapulars are beautifully marked with black and yellow: quills dusky;

dusky; the edge of the first, and tips of the secondaries, white; and those next the back barred with black and pale red: breast and belly white: tail coverts long, of a reddish brown, and almost cover the tail, which consists of sourteen feathers, black on their lower part, then crossed with a bar of deep orange, another narrow one of black, and the ends white or pale orange: the vent of a dull yellow: legs pale green: toes divided to their origin.

We fearce know of any bird which is so universally spread over the surface of the globe as this species; being mentioned by most voyagers, as well as brought into England from such variety of places. It is seen throughout the old continent from the arctic regions of Sibiria to the Cape of Good Hope, at which last place it is pretty common. It also inhabits the islands of Ceylon and Japan. In America it is met with almost without exception, particularly in South Carolina, where it swarms *. I have also seen a specimen which came from Cayenne, and been informed that it is likewise at Surinam. I have received it myself from Jamaica. Said to be extremely common in Falkland Islands, even more so than in England †.

With us it disappears as the spring advances; but we have just reason to suppose that the whole of them do not depart England, the nest being frequently sound in the sens and marshes in many parts of this kingdom ‡. The nest is composed of dried plants, with a few feathers. The eggs, sour or sive in number,

[‡] Both this and the Jack Snipe are to be found the whole year through in Cumberland. Dr. Heysbam.—In the fens of Lincolnsbire, Wolmar Forest, Bodmyn Downs. Barring. Misc. p. 211.—I have been informed that it breeds in several of the islets, called Aytes, of the river Thames.

oblong, of a dirty olive-colour, marked with dusky spots. When disturbed, in the breeding season, soars to a vast height, making a singular bleating kind of noise; and when they descend, dart down with vast rapidity. The male also (while his mate sits on the eggs) often poises himself on his wings, making sometimes a whistling, and sometimes a drumming noise. They seed on small worms, and other insects, which they find in the moist ground; as also on small snails; having sound the last whole in the stomachs of both this and the next species. They are dressed without exenterating, as the Woodcock, and are accounted delicate.

DESCRIPTION.

THIS is half as big as the former, and weighs fcarce two ounces: length eight inches and a half. Bill above an inch

· Br. Zool.

and

and a half long, and black: crown of the head black, tinged with ruft-colour: over each eye a yellow ftreak: neck varied with white, brown, and pale red: fcapulars narrow, long, and of a brown colour, margined with yellow: the rump of a gloffy blueish purple: belly and vent white: greater quills dusky: tail brown, with tawny edges, and consists of twelve feathers: legs cinereous green.

This species is either less common than the former, or not so well ascertained by the different voyagers; as I cannot trace it more south than Aleppo, where it is not uncommon *, and to the north as far as lat. 80. 27 †. It is sound both in Europe and North America. I suspect likewise, from a passage in Fermin ‡, that it inhabits Surinam. The manners are much like those of the last species.

PLACE AND MANNERS.

^{*} Ruffel Alep. p. 65.

⁺ Phypps mentions a low flat isle off Waygats, which "abounds with a small Snipe, similar to the Jack Snipe in England." See Voy. p. 53.

[†] Hist. Surin. vol. ii. p. 189, 190.—He there talks of a large and a small Snipe: the first is rusous, black, and ash-colour, mixed: breast and belly ash-colour: it is smaller than the Partridge, and slies slowly, but runs quick. The small one he describes much like ours; and says, they are seen by thousands on the sea shores; that it must be a bad marksman that does not kill sixty at once, with sine shot; and that he has killed eighty-sive with a single charge. The sless of both is accounted very delicate; but the last is so small that a man may safely eat twenty at a meal.

CAPE SN.

Scolopax Capensis, Lin. Syst. i. p. 246. 14. La Becassine du Cap de B. Esperance, Bris. Orn. App. p. 141. pl. 6.—Bust. Ois. vii. p. 494.—Pl. Enl. 270.

DESCRIPTION ..

CIZE of our Snipe: length ten inches. Bill one inch and threequarters; colour of it reddish brown: the crown of the head is ash-colour, crossed with streaks of black: down the middle is a pale band from the base of the bill to the hind head: round the eyes white, ending in a streak behind: the under part is bounded by a black line; the rest of the head and neck rusous: at the top of the breaft a narrow band of black; from this all the under parts are dusky white: the upper part of the body, wings, and tail, are ash-colour, transversely waved and crossed with black; most regular on the wing coverts, each feather of which ismarked with four or five yellowish bars on the inner web, and as. many round spots of the same on the outer: the tail feathers: are also marked in the same manner; the four middle feathers. having bars of the yellowish colour, and the four outer ones oneach fide fpots, as in the quills: the inner edge of the wing, in the course of the scapulars, streaked with white: legs dusky.

PLACE.

Inhabits the Cape of Good Hope.

VAR. A.
PL. LXXXI.
DESCRIPTION.

THE top of the head, throat, and fore part of the neck, are rufous chefnut: chin almost white: the eye surrounded with black, and placed in a large bed of white, pointing to the hind head; the rest of the head, neck, and breast, black: the back, rump, wing coverts, and second quills, dark olive green, elegantly mottled and barred with dusky: scapulars white: the two middle

Cape Snipe Var. A.

middle tail feathers like the back; the others, and greater quills, dufky black, marked with large orange fpots, five or fix on each feather: belly, thighs, and vent, white: bill and legs pale brown.

The description and figure of this variety is taken from a painting by the late Mr. Edwards, now in my possession.

La Becassine de la Chine, Buf. Ois. vii. p. 495 .- Pl. Enl. 881.

VAR. B.
DESCRIPTION.

SMALLER than the common Snipe: length ten inches. Bill yellow, with a dusky tip: top of the head brown, mixed with black: down the middle of the crown, and over each eye, a stripe of white: the chin white: the rest of the head and neck mixed grey and pale brown: the fore part of the neck is streaked perpendicularly; and the back part, and all round the bottom, transversely: the upper part of the body and wings delicately mixed and waved with blueish grey, brown, pale rusous, and black: breast and under parts white: quills dusky, marked with oval cream-coloured spots: tail blue grey and dusky mixed, with three or four roundish cream-coloured spots on each feather, surrounded with black: legs grey.

Inhabits China.

PLACE.

La Becassine de Madagascar, Buf. Ois. vii. p. 495.—Pl. Enl. 922.

VAR. C.

Description.

LENGTH ten inches. Bill of a brownish red; strait, except towards the end, where it bends a trisse downwards: round the eye white, passing a little way down the neck on each side; above this a black streak: the chin white: rest of the head and neck rusous: the lower part of the neck and back undulated

with

T 2

with black and grey: wing coverts finely undulated black and ash-colour: the second quills and tail are undulated grey and black, with three or sour oval spots of a pale rusous, encircled with black: the great quills are banded with rusous and black alternately: the under part of the body white: legs the colour of the bill.

PLACE.

Inhabits Madagascar.

9. Var. D.

DESCRIPTION.

SIZE of the last: length eight inches and a half. Bill shorter than in the others; colour of it and the irides yellow: crown of the head white: round the eyes the same, passing towards the hind head, and ending in a point: sides of the head, throat, and neck, deep brown: upper part of the back, the scapulars, and wing coverts, green: lower part of the back and rump, the upper tail coverts, and under parts of the body, white: prime quills purple; the outer webs marked with five orange spots: the secondaries are green, and as long as the greater quills; the one nearest the body white: tail purple, marked with orange spots: legs of a greenish yellow.

PLACE.

Inhabits Bengal. I have scarce a doubt of this being a further variety of the Cape species.

La Beccasine de Madrast, Bris. Orn. v. p. 308. 4.—Bas. Ois. vii. p. 496. Partridge Snipe, Rais Syn. p. 193. pl. 1. sig. 2.

MADRAS SN.

THIS has a pale rufous bill: the upper parts mixed with fulvous and blackish: down the middle of the crown a blackish brown stripe; and on each side of the head, behind the eye, another: on the back are two black brown bands: the throat and fore part of the neck sulvous, marked with blackish spots: the rest of the under parts white, except a band of black across the breast: the quills and tail are variegated with black, sulvous, and grey: the hind toe of equal length with the fore ones. Inhabits Madras.

Description.

Red-breasted Godwit, Edw. pl. 138.—Br. Zool. Nº 181. pl. 77.—Ara. Zool. Nº 372.

Br. Muf. Lev. Muf.

DESCRIPTION.

ENGTH eighteen inches: weight 12 ounces. Bill three inches and three quarters, rather inclining upwards; colour dusky, inclining to yellow next the head: the head, neck, breast, and upper part of the back, are ferruginous, streaked with black, except the neck, which is plain: over the eyes a streak of a paler colour:

colour: lower part of the back and rump rufous white; the feathers dufky down the shafts: the upper tail coverts are barred rufous, white, and brown: the lesser wing coverts are brown, fringed with white; the greater ones plain, and of a darker brown; some of them tipped with white, forming a bar on the wing: greater quills black on the outer webs, white towards the base within: the secondaries half white, half black: the tail of the same colours: legs black.

This species seems to be most plentisul in America, being found in numbers in the sens about Hudson's Bay, where they breed, and then retire southward. The natives know it by the name of Pusquatishishue. It now and then appears in England, but is very rare*. It is however more plentisul on the continent. Is sound in Lapland +. Appears about the Caspian Sea in spring; but is never seen in Sibiria, nor in the north of Asia ‡. It is said to be a fine-slavoured bird.

PLACES.

Lev. Mus.

A TRIFLE bigger than the last. The bill four inches and a half in length, and turns much upwards; colour dusky, with the base reddish, and the point nearly black: the upper parts of the body plain brown: head and neck cinereous: chin nearly white: over the eye a pale streak: breast mottled with red: from thence to the vent white: tail as in the last described: legs dusky.

VAR. A.

DESCRIPTION:

^{*} The Br. Zool. mentions its being once shot near Hull; and Mr. Tunstall has a specimen in his collection which came out of Dorses bire.

[†] Linnæus.

Br. Mus. Lev. Mus.

DESCRIPTION.

ENGTH fixteen inches: weight twelve ounces. Bill four inches long, bending a little upwards; the base half pale purple, from thence to the end black; the under mandible shortest; from the base, passing over the eye, a whitish streak: the head, neck, and upper parts, reddish brown, each feather marked down the middle with a dark spot: belly and vent white: the six prime quills are black; the inner edges reddish brown; the shaft of the first white, most of the others brown; the outer margins pale, and clouded with pale brown; the inner webs whitish, banded with greyish brown: the tail feathers are white; the two middle barred with brown; the others the same on the outer web, and the inner likewise towards the tips only: legs dusky. In some birds the rump is white, and the chin nearly so.

PLACE AND MANNERS.

This bird is found in England, at the same time with the Ruffs, and taken with them promiscuously, a Stale-Bird being placed as for the others; but the Godwit continues with us the winter through, walking on the open sands, like the Curlew, and seeds on

insects.

^{*} This circumstance has also been observed by Mr. Pennant, in the Br. Zool. but thinks it may be mere variety.

insects*. It is likewise met with in various parts of the continent of Europe and Asia, as well as in America.

La grande Barge rousse, Bris. Orn. v. p. 284. 6.—Buf. Ois. vii. p. 505.— Pl. Enl. 916.

VAR. A.

Barbary Godwit, Shaw's Trav. p. 255.

THIS bird is fifteen inches long, and has a bill like the laft. It is dusky on the upper parts; the feathers edged with rufous: over the eyes a streak of rusous white: the throat and neck are rusous: lower part of the back and rump white, marked with dusky spots: upper tail coverts and tail barred black and white: under parts from the breast white: under tail coverts and sides marked with transverse black spots: thighs plain: some of the outer wing coverts edged at the ends with white: quills black, with the shafts white; the three first marked with a transverse white spot one third from the end: secondaries edged and tipped with rusous: legs greenish brown.

DESCRIPTION.

Said to inhabit England. It is probably a mere variety of the last. I have observed them to vary much; and this seems to differ in sex: at least there are two birds in the Leverian Mufeum, which were there placed as male and female, and answer to the description of these last birds: one of them has the breast of a pure white, the other pale rusous.

Barker, Albin, ii. pl. 71? Spotted Redshank, Br. Zool. No 186.

DESCRIPTION.

SIZE of the Greenshank. The head of a pale ash-colour, marked with oblong streaks of black: back dusky, varied with triangular white spots: wing coverts ash-coloured, spotted in the same manner: quills dusky: breast, belly, and thighs, white; the first thinly spotted with black: the middle seathers of the tail ash-coloured; the side seathers whitish, barred with black: legs long, and of a bright red.

PLACE.

Inhabits various parts of the continent of Europe; and has been met with, though rarely, in England.

* Sondmaer, Strom. 235. † Arct. Zool.

Spotted Woodcock, Phil. Trans. vol. lxii. p. 410. Spotted Snipe, Art. Zool. No 374.

Lev. Mus.

+ VAR. A.

THIS is larger and longer than the Greenshank: in length near fixteen inches. The bill more than two inches long, and brown: orbits, chin, and throat, white: from the bill to the eye a line of white: cheeks and fore part of the neck white, with short dusky streaks: crown and upper part of the neck brown, streaked with white: wings black, marked with elegant triangular spots of white: breast and belly white: legs long, and in the living bird of a rich yellow; sometimes red.

Description.

This is found in North America, and is common at Hudson's Bay: comes into the neighbourhood of Albany fort, the end of April or beginning of May, and departs the end of September. Frequents the banks of rivers, feeding on small shell-fish and worms. On its return towards the south stops at New York for a time, but proceeds more southward, in order to pass the winter. The natives call this species Sa-sa-shew; the English, Yellow-legs. This, and several other species of Snipes and Sandpipers, are called, in North America, Humilities*.

PLACE AND MANNERS.

My specimen seems stronger marked; with less white about the head than in the above, and the spots on the wings very distinct; but the prime quills are dusky, and not spotted: the bill is two inches and a quarter long, brown, shaped exactly as that of the Greenshank: the legs yellowish brown. I received this from Hudson's Bay, and esteem it as differing in sex only from the last described.

Albin, iii. pl. 87.—Br. Zool. No 184. pl. 65.

Br. Mus. Lev. Mus.

DESCRIPTION.

LENGTH twelve inches. Bill almost two; base reddish; end dusky black: irides reddish hazel: head and hind part of the neck dusky ash-colour: back and scapulars glossy greenish brown: wing coverts ash-colour, mixed with dusky and brown, and marked with whitish spots: ends of all the secondaries, except the two inner ones, white for an inch at the tip: quills dusky; four or five of the inner ones more or less tipped with white, with dusky margins: over the eye a streak of white; and between the bill and eye a dusky mark: chin and fore part of the neck marked with short dusky streaks: the under parts from the breast, and the lower part of the back and rump, white, marked with minute dusky specks: tail coverts and tail crossed with numerous bars of black, twelve or thirteen on each feather: legs orange: claws black. In some birds both the rump and belly are of a pure white.

PLACE AND MANNERS.

The Redshank is pretty common in this kingdom, but grows fcarcer towards the north. It breeds, like many others of this genus, in the marshes; and lays four whitish eggs, tinged with olive, and marked with irregular black spots, most numerous at the large end. When disturbed it has the actions of a Lapwing, slying round its nest, which it is said to do in a circular manner,

and

and this regular, with the nest in the centre, be the circuit larger or smaller; insomuch that an attentive observer will often find it out by this circumstance. It is common also in many parts of *Europe*, as high as *Finmark*; and is likewise found in *Sibiria**: is indigenous also to the *American* continent.

BILL black; bare, reddish, as in the Redsbank: irides blue: head, hind part of the neck, and back, greyish: chin, throat, breast, and belly, white; sides of the three first marked with small dusky spots: over the eyes a line of white: wings dusky: the outer webs of the coverts and secondaries barred with white and black; shaft of the outer quill white: rump and tail barred black and white: legs orange red.

Inhabits the marshes of China. From the drawings of the late Dr. Fothergill.

Scolopax candida, Lin. Syst. i. p. 247. 18. Le Chevalier blanc, Bris. Orn. v. p. 207. 8.—Bus. Ois. vii. p. 519. White Redshank, Edw. pl. 139.

SIZE of the Redshank: length eleven inches. Bill almost two, of an orange-colour, with the tip black: the upper part of the head, neck, back, scapulars, lesser wing, and upper tail coverts, are white, varied with transverse rusous grey streaks: fore part of the head, throat, and from thence to the vent, as also the rump, pure white: greater wing coverts dirty white: prime quills grey: secondaries and tail white, spotted transversely with rusous grey: legs orange.

PLACE.

This was met with at *Hudson's Bay*; and, on our further acquaintance with it, is not unlikely to prove a mere variety of the *Redshank*.

SEMIPALMAT-ED SN. Semipalmated Snipe, Ara. Zool. Nº 380.

DESCRIPTION.

ENGTH fourteen inches. Bill two inches long, dusky: head and neck streaked black and white: breast white, marked with round black spots: belly and sides white; the last crossed with transverse bars of brown: back and wing coverts cinereous, with great sagittal spots of black: primaries dusky, crossed with a white bar: secondaries white: the middle feathers of the tail cinereous, barred with black; outmost white: legs dusky: toes semipalmated.

PLACE.

Inhabits New York.

STONE SN.

Stone Snipe, Ara. Zool. No 376.

Description.

WICE the fize of a Snipe. Bill black: head, neck, breaft, back, fcapulars, and greater coverts, fpotted black and white: rump and tail barred with the fame: primaries dufky: legs long and yellow.

PLACE.

Observed in autumn, feeding on the sands on the lower part of *Chateaux Bay*, and are called *Stone Curlews*. Are perpetually nodding their heads.

YELLOW-SHANKS. Yellowshanks, Art. Zool. No 378.

DESCRIPTION.

ENGTH eleven inches. Bill stender, black, a little bent at the end: head, hind part of the neck, back, and greater wing

wing coverts, dirty white, spotted with black: lesser coverts plain brown: primaries dusky: breast and fore part of the neck spotted black and white: belly and tail coverts white: tail barred brown and white: legs yellow.

Appears in the province of New York in autumn.

PLACE.

NODDING SN.

DESCRIPTION.

Nodding Snipe, Ara. Zool. No 370.

SIZE of the common Snipe. Bill slender, long, black: crown and upper part of the back dusky, streaked with red: cheeks cinereous, streaked with black: neck and breast cinereous, mixed with rust-colour, and marked with obscure dark spots: belly white: thighs spotted with black: lesser wing coverts ash-coloured; greater dusky, edged with brown: quills dusky; the secondaries tipped with white: lower part of the back white, spotted with black: tail barred black and white; tip reddish: legs green.

Observed in Chateaux Bay, on the coast of Labrador, in September. Are perpetually nodding their heads.

PLACE.

Black Snipe, Ara. Zool. No 381.

BILL and legs red: plumage most intensely black.
Observed by Steller in the islands towards America.

ish: the toes bordered by a narrow plain membrane.

DIISKY SN

Dufky Snipe, Arct. Zool. p. 471. 6.

TENGTH almost twelve inches. Bill two inches and one third, Descriptions a little bent downwards at the point; colour black; the base of the lower mandible pale: plumage on the upper part of the body dusky black; the edges of the feathers whitish: crown darkeft, and plain: fcapulars and leffer wing coverts marked with whitish spots on the margins: lower part of the back and rump white: cheeks, throat, and fore part of the neck, deep ash-colour: from thence to the vent the fame, but growing lighter as it approaches the last, and here and there mixed and edged with white: quills brown, paleft within, and fpotted with grey on the outer margin, and fome of the fecondaries on both webs: the two middle tail feathers dusky brown, marked with transverse whitish streaks; the others brown, crossed in the same manner with white: legs brown.

Breeds within the Artic circle. Migrates into Russia and Sibiria.

PLACE.

Scolopax cinerea, N. C. Petr. vol. xix. 6. t. 19. (J. Gueldenstaedt.) Terek Avoset, Ara. Zool. p. 502.

TEREK SN.

ENGTH nine inches. The bill bends upwards from the base, and a little downwards at the tip, and is nearly two X 2 inches

DESCRIPTION.

inches in length; colour of it black: irides brown: the plumage on the upper parts is wholly cinereous; the middle of each feather brown, which is in streaks on the head and neck, on the back oblong, and on the rump transverse: the under parts white; but the throat and breast streaked with ash-colour: wings ash-colour, crossed with a bar of white: quills brown; the shaft of the first white, the second cinereous: secondaries tipped with white: the two middle tail feathers are cinereous; the rest the same, varied with whitish, but not banded: legs reddish brown: toes somewhat palmated at the base: claws blackish.

Male and female alike.

PLACE AND MANNERS. This inhabits, during the fummer, the neighbourhood of the Caspian Sea, particularly about the mouth of the river Terek, where it breeds. Met with in flocks in the marshes, especially on the borders of salt lakes, and feeds on insects. This seems not perfectly consonant to any genus: seems a link between the Snipe and Avoset: but, in our opinion, the bill turning downwards at the point, seems to forbid the placing it with the latter; though the feet being palmated gives it great affinity.

CAURALE SN.

Le Caurâle, ou petit Paon des Roses, Buf. Ois. viii. p. 169. pl. 14.—Pl. Enl. 782.

Lev. Mus.

DESCRIPTION.

THIS is a most beautiful species: is about the size of the Whimbrel, and measures sisteen inches in length. The bill is near two inches long, of a yellowish green, and bends a very trisle downwards: the head and sides below the eyes are black: over the eye is a streak of white; and the black is bounded beneath by white, passing from the chin and throat to the hind head; in the

the middle of this white, on each fide, in the direction of the jaw, is a black flender line: the neck and breaft are rufous, ftriated transversely with flender black lines: back the same, but more grey, crossed with broad bars of black: scapulars grey, banded with white: the wings are cream-colour, mottled with black near the shoulder, and beautifully banded with rufous red; in the middle, and at some distance from the end of the quills, in both places accompanied with black: the tail is grey, mottled and striated across with black interrupted bands; and near the end crossed with a broad bar of black, bounded above with rusous red: the belly, thighs, and vent, are white: legs yellow, and rather short for the size of the bird.

This inhabits the interior parts of Guiana, but is not common. It frequents the fides of rivers: is a folitary bird, and known by a kind of plaintive whiftle, which the natives imitate, in order to decoy the bird within reach. The specimen in the Leverian Museum is a most perfect and fine-coloured one. I have seen three or four others, which were less brilliant in their plumage. Hence we may suspect that the male may differ from the female merely by this circumstance; and that Sir Ashton Lever's bird is a male. The inhabitants of Guiana give this species the name of Paon des Roses. One which came under my inspection had a label affixed, with the name of le Pard.

Br. Mus. Lev. Mus.

I ENGTH one foot. Bill more than one inch, yellowish; DESCRIPTION. in fome black: the whole face covered with numerous yellow pimples: irides hazel: the back part of the head, and the neck, are furnished with very long feathers, standing out in a remarkable manner, not unlike the ruff worn by our ancestors; a portion of this set of feathers stands up over each eye, imitating ears: the ruff is of as many different colours as there are birds who wear it, no two being alike; in general it is barred with black, yet I have feen many white, or of one plain colour; and I observe, that of whatever colour the ruff may be, the breast is very little different; and the transverse markings on the upper parts of the plumage fomewhat correspond: the ground colour, however, is mostly brown; the feathers in general barred with black, and many of them marked with concentric circles of black: quills dufky: lower belly, vent, and upper tail coverts, white; the last pretty long: the four middle tail feathers barred

not unlike the back; the others plain brown: the legs in all are dull yellow: claws black.

FEMALE.

The female, or Reeve, wants the ruff on the neck, and is less than the male. General colour brown: the middle of each feather dusky, in some parts almost black; the edges of the feathers very pale: primaries dusky or black: secondaries barred rusous brown and black: belly, vent, and upper tail coverts, white: tail dusky: legs as in the male.

The male bird does not gain the ruff till the fecond feason, being till then like the female; as he also is from the end of June till the feason of love commences, when nature clothes him with the ruff, and the red pimples break out on the face; but after the time of incubation the long feathers fall off, and the caruncles shrink in under the skin, so as not to be discerned.

PLACE AND MANNERS.

These birds inhabit the north of Europe in summer, as far as Iceland, as well as the northern marshes of Russia and Sibiria. They arrive in England in the spring, chiefly in Lincolnshire*, the isle of Ely, and the East Riding of Yorkshire. The males are in much greater number than the females; hence the continual battles for the sake of possession. The male chuses a stand on some dry bank near a splash of water, running round a particular spot so often as to make a bare circular path: the moment a female appears, all the males within a given distance begin sighting, at which time the sowiers catch them, by means of nets, in great numbers +. They are also caught by means of Stale Birds, but

[·] Chiefly in the West Fen. Tour in Scotl.

[†] By placing a clap-net, fourteen yards long and four broad, over night, forty-four birds have been caught at one pull, the morning following; and in all fix dozen in the course of the morning.—A fowler has caught between forty and fifty dozen in one season.—Br. Zool.

in much less quantity. It is usual to fat these birds for the table by means of bread and milk, mixed with bemp-seed, and sometimes boiled wheat, to these by many sugar is added; which last in a fortnight's time will cause them to be one lump of fat, when they will fetch from two shillings to half a crown each. The Reeve lays four eggs in a tust of grass, the beginning of May; they are white, marked with large rusty spots: and the young are hatched in about a month. It is not known for certain where this species pass the winter, and perhaps it may be some time before we do; for, as the bird has the characteristic marks of the Rust only in breeding-time, it may possibly pass unheeded among the several others of this genus. In the Leverian Museum is a variety of the semale, being wholly white, except the wings, which have much the same marking as usual, except of a very pale colour.

ENGTH thirteen inches and a half: weight eight ounces.

Bill one inch or more, and black: irides hazel: the crown of the head is gloffy greenish black; at the back part springs a crest composed of narrow feathers, some of which are sour inches in length, and turn upwards at the ends: round the eye and the Vol. III.

± LAPWING,

DESCRIPTION.

fides of the neck white: beneath the eye a streak of black: fore part of the neck, as far as the breast, black; hind part white and brown: the back and wings green; the first glossed with purple, the last with blue: quills black; the four first have a white spot at the tip: the base half of the secondaries white: breast and belly white: upper tail coverts and vent pale rusous: tail white, for half way next the base; the end half black; the outer feathers almost wholly white: legs brownish red.

Male and female alike, but the last is rather smaller.

PLACE AND MANNERS. This species is pretty common in England, where it remains the whole year. They lay their eggs on the ground, scraping together a little dried grass for a bed; they are sour in number, of a dirty olive, spotted with black. The hen sits about three weeks: the young run within two or three days after they are hatched. The female has great address in decoying the curious impertinent from the nest or young, using many stratagems of deceit; slying over the head of any one with great noise: is said to be most clamorous when farthest from the nest; and will even feign to run along the ground, as if lame, in order to decoy. Towards winter both young and old collect in slocks of four or five hundred, or more, and are seen on our heaths; and in some places are taken in nets, for the use of the table*. Their eggs are also thought a delicacy, and fetch a good price †.

These are also common in most parts of Europe, as far as

^{*} In the provinces of *Brie* and *Champaign*, in *France*, are feen in vaft flocks of thousands, and decoyed into the nets by the playing of a mirror, with the addition of some stuffed birds, with here and there a live one intermixed. *Hist. des Ois*.

[†] Three shillings per dozen. - Br. Zool.

Iceland; and on the continent. Change place according to the feason; being met with in the winter in Persia and Egypt. We have also seen a specimen from China. The chief sood of the bird in its wild state is worms, which it draws out of the ground morning and evening. It is frequently kept in gardens, of which it is a useful inhabitant, freeing them from worms and slugs, and in time becoming tolerably familiar. I have seen this bird approach a worm cast, turn it aside, and after making two or three turns about, by way of giving motion to the ground, the worm came out, and the watchful bird seizing hold of it drew it forth. During frosty and hard weather, this pretty gardener will seed on bits of pudding, meat, and such like; but ever forsaking these when worms can be had, its most esteemed food.

Le grand Vanneau de Bologne, Bris. Orn. v. p. 110. 5.

GREATER LAP-WING.

BIGGER than a Lapwing. Bill yellowish, with the tip black: head and hind part of the neck chesnut: back, wings, scapulars, and rump, black: throat, fore part of the neck, and breast, white, marked with ferruginous spots: belly, sides, and thighs, white: quills and tail black: legs the colour of yellow oker.

DESCRIPTION.

Inhabits Italy, about Bologna, where it is called Ginocchiella.

PLACE.

DESCRIPTION.

SIZE of the Lapwing: length twelve inches. Bill yellowish green, with the tip black: the forehead covered with a yellow skin, as in the Louisiane species, but not taking in the eye: the forehead is white: chin and throat black: the head and upper parts of the neck, body, and lesser wing coverts, grey brown: the under parts the same, but paler: lower part of the belly, upper and under tail coverts, dirty white: the greater wing coverts the same: quills black, more or less white at the bottom: at the bend of the wing a black spur: tail, half way from the base, dirty white; the rest of the length black, with pale rusous tips.

PLACE.

This species inhabits Senegal.

It was perhaps these that interrupted Mr. Adanson's shooting, as they alarmed all the birds within hearing by their cries. The Negroes called them Uett Uett; the French, Squallers; because, as soon as they see a man, they set up a loud screaming, on which all other birds take the hint, and sly off. He says that they always sly in pairs, and have a spur on each wing *.

Lev. Mus.

DESCRIPTION.

ENGTH ten inches. Bill one inch and a half long, black: top of the head and hind part of the neck dusky ash-colour: over the eye a pale streak; and between the bill and eye dusky: back and wings greenish glossy brown; the edges of the seathers spotted with dirty white: chin white: fore part of the neck dusky white, marked with dark streaks: from thence to the vent white; as are the upper and lower tail coverts: quills and outer edge of the wing plain dusky brown: secondaries nearly as long as the quills: under the wings dusky, the seathers barred with white, the bars meeting obliquely, and forming the shape of the letter V: the tail is white, the seathers more or less barred with dusky; the outer one least of all: the legs are of a greenish lead-colour, slender: the outer and middle toes united at the base by a membrane.

PLACE.

This bird is common to many parts of Europe, and is for the most part a solitary species. It frequents fresh waters and streams. Is very plenty in the watery places of Russia and Sibiria; and is sound as far as Iceland. It is also in England, though rather scarce; and I am not clear that it is seen, except in the winter season, having never heard of the circumstance: nor is it

ever

ever met with in greater numbers than four or five together. Is found also in America. This has a musky kind of smell, not unlike some of the Petrel genus.

Tringa littorea, Lin. Syst. i. p. 251. No 17.—Faun. Suec. No 185.—Brun. No 177. 178.—Muller, No 200.

VAR. A.

Le Chevaller cendré, Bris. Orn. v. p. 203. 7. pl. 17. fig. 2. varié, Buf. Ois. vii. p. 517.—Pl. Enl. 300.

Mr. Oldham's white Heron, Albin, iii. pl. 89. Shore Sandpiper, Art. Zool. p. 481. F.

THIS differs not materially from the other. The spots on the back are ferruginous instead of white: the shaft of the first quill is white, as in that bird; and the secondaries have white tips: the legs are brown.

DESCRIPTION.

This bird is faid to migrate from Sweden into England at the approach of winter*.

PLACE.

Brunnich mentions a further variety, wherein the first quill has a black shaft, and the spots on the back and wings less: and obferves, that they differ in age and sex.

ENGTH ten inches. Bill one inch and a quarter long, and black: head and hind part of the neck pale ash-colour: through the eye a dusky streak: forehead white: over the eye a line of the same: back and wings cinereous, marked with whitish spots, not very conspicuous: sides of the head, and under parts, dirty white; across the breast verging to ash-colour: quills dusky: tail the same; all but the two middle feathers barred with white on the outer webs: legs dusky green.

Inhabits

172

PLACE.

Inhabits King George's Sound. In the collection of Sir Joseph Banks.

wood \$.

Tringa glareola, Faun. Suec. Nº 184. Wood Sandpiper, Ara. Zool. p. 482. G.

DESCRIPTION.

HIS is said to equal a Starling in size. Back brown, dotted with white: rump and belly white: quills brown; the shaft of the first white: secondaries white at the tips: tail banded brown and white; the outer feathers least brown in them.

PLACE.

Inhabits the moist woods of Sweden.

WHITE-WING-ED S.

DESCRIPTION.

A TRIFLE bigger than the Purre: length eight inches and a half. Bill one inch, cinereous: irides dusky brown: over the eye a pale streak: the head, hind part of the neck, back, and wings, are brownish black: lesser wing coverts dusky black: from the bend of the wing an oblique streak passes over the wing coverts; the greater ones mixed ferruginous and black: quills black, and reach almost to the end of the tail: the throat, breast, belly, and rump, are rusous: vent dirty yellow: the two middle tail feathers deep blackish brown; the others barred black and rusous; the outer feathers only on the exterior webs: legs dusky green.

PLACE.

This inhabits Otaheite, near the rivers, and is called Torowe. Also met with at Eimeo, or York Isle, and is there called Te-te.

VARIETIES.

This bird varies. In one specimen which came under my view, the crown of the head was dusky: the line over the eye ferruginous; and a tinge of the same was visible throughout the whole of the plumage: bill and legs yellowish.

6

White-winged Sandpiper ?

In another all the leffer wing coverts were white: four of the middle tail feathers plain; the others barred as usual: but all had the streak over the eye.

Pr. LXXXII.

Tringa maritima, Brun. Nº 182.-Muller, Nº 206.-Leems Lap. Nº 254. Selninger Sandpiper, Ara. Zool. p. 480. C.

SELNINGER S.

SIZE of a Starling. Upper parts varied with grey and black: DESCRIPTION. middle of the back tinged with violet: fore part of the neck dusky: under part of the body white: tail dusky: the four outer feathers shortest, and edged with white: legs yellow.

Inhabits Norway and Iceland. Lives about the sea shores, and emits a piping note.

PLACE.

Tringa undata, Brun. Orn. p. 55. No 183. Waved Sandpiper, Ara. Zool. p. 481. E.

16. WAVED \$.

CENERAL colour dusky, undulated with luteous and white: wing coverts and fecondaries tipped with white: rump white: tail cinereous, and margined with black at the tip: the first prime quill has a white shaft.

DESCRIPTION.

Inhabits Denmark and Norway.

PLACE.

Tringa rostro brevi nigro, tota diluté cinerea, Muller, Nº 205. Uniform Sandpiper, Arat. Zool. p. 482. H.

UNIFORM S.

HIS species has a short black bill; and the whole of the plumage of an uniform pale ash-colour.

DESCRIPTION.

Inhabits Iceland.

PLACE.

174

18. DUSKY S.

Tringa calidris, Lin. Syst. i. p. 252. 19. La Manbeche, Brif. Orn. v. p. 226. 14. pl. 20. fig. 1.—Buf. Oif. vii. p. 529. pl. 31.

Description.

SIZE of the Redshank: length nine inches and a quarter. Bill one inch and a half, and black, with the base pale: the plumage on the upper parts is brownish black, the feathers margined with pale chefnut: the rump cinereous brown, transversely ftreaked with black, the margins of the feathers white: the under parts of the body chefnut*: fides transversely streaked with pale chefnut and white: tail greyish brown; all except the two middle feathers margined with white: legs brown: the outer and middle toe united to the first joint.

PLACE.

This species is spoken of by authors as a bird of both France and Germany; but is not, as we hear of, in England. It frequents the fea shores, picking up the food there: further than this the manners are unknown. We have feen one quite corresponding with the above description, except that the under parts were white: this came from Gibraltar.

19. FRECKLED S. La Manbeche tachetée, Bris. Orn. v. p. 229. 15. pl. 21. fig. 1. Buf. Ois. vii. p. 531.-Pl. Enl. 365. Freckled Sandpiper, Art. Zool. p. 480. B.

DESCRIPTION. A TRIFLE less than the Redshank: length nine inches. Bill dusky: the upper parts of the body ash-colour, spotted with red and black; the last glossed with violet: beneath reddish

* Linnæus calls it olive.

white,

white, varied with dufky and chefnut spots: the two middle tail feathers cinereous, edged with white; the rest the same, but darker: the outer feathers marked lengthways on the exterior web with a white line: legs greenish.

Inhabits France, the north of Russia, and Sibiria.

PLACE.

La Manbeche grife, Brif. Orn. v. p. 233. 16. pl. 21. fig. 2.—Buf. Oif. vii. p. 531.—Pl. Enl. 366.

GRISLED S.

SIZE of the freckled Sandpiper: length nine inches and a quarter. Bill more than one inch, and black: the plumage above is grey, the feathers with paler edges; but those of the upper part of the back and scapulars plain grey; of the rump pale grey, marked with a double brown band parallel to the margin, which is white: the under parts are white; but the seathers of the neck, breast, and sides, marked with a waved brown band parallel to the edge; and those of the belly with a longitudinal brown line near the end: quills brown, edged with a paler colour; the ten first with white shafts: the secondaries grey; and the five next the body marked with a brown band parallel to the margin: tail grey, with white margins; and parallel to them a deep grey band: the legs black.

Description:

Inhabits Europe: found among its congenera on the fea coasts.

PLACE.

STRIATED S.

Tringa striata, Lin. Syft. i. p. 248. 5.—Muller, Nº 194.—Faun. Groenl. Nº 73.

Le Chevalier rayé, Bris. Orn. v. p. 196. 5. pl. 13. fig. 1.—Buf. Ois. vii. p. 516.—Pl. Enl. 827.
Striated Sandpiper, Art. Zool. No 383.

Description.

one inch and a half long; the base half red, the end black: the upper part of the body undulated with dusky and cinereous: fore part of the neck dusky: breast and belly white: primaries and secondaries black, the last tipped with white: tertials white, with a stripe of black: tail black: the feathers on the side cinereous, edged with white: legs orange.

Linnæus fays, the rump and tail are white; the last fasciated with brown: and that the under parts are white, marked with both longitudinal and transverse stripes: possibly this may differ in sex, if the same bird.

PLACE AND MANNERS.

This inhabits the colder parts of Europe; being found in Sweden and Norway. Is found, but less frequent, in Rusha and Sibiria, though it is met with even in Iceland and Greenland: in the last place the winter throughout; running backwards and forwards on the shore, according as the waves approach or recede, feeding on such insects as are lest on the beach. Often skims along the surface of the water, like a Swallow, catching insects; rising and falling with the waves, but ever avoiding coming in contact with them. In breeding-time retires within shore, and lays from four to six eggs, a little bigger than those of the Starling, marked with pale obscure spots. Twitters like the Swallow. Is not a very shy

shy bird: often caught in snares; and the slesh is accounted good food. The feathers used for stuffing, like other feathers.

Le Chevalier tacheté, Bris. Orn. v. p. 200, 6.

VAR. A.

DESCRIPTION.

THIS is smaller than the last. The upper parts of the head, neck, and back, are blackish, margined with rusous grey: scapulars the same, but barred with grey on the sides: lower part of the back and rump white: fore part, as far as the breast, mixed black and white; verging to rusous on the sides: breast and belly white, marked with minute black spots: lower belly plain white: wing coverts grey brown; some of them crossed at the end with rusous grey and black: quills dusky, within hoary; shaft of the first white: upper and under tail coverts, the sides, and tail, barred black and white. This seems much allied to the last, though varying somewhat in description. Brisson's two sigures seem to differ not sufficiently to form two distinct species.

Tringa cinerea, Brun. No 179.—Muller, No 202.—Frisch. t. 237.

Ash-coloured Sandpiper, Br. Zool. ii. p. 194.—Art. Zool. No 386.

ASH-COLOUR ED S.

LENGTH ten inches: weight five ounces. The head is ash-colour, spotted with black: neck the same, marked with dusky streaks: back and wing coverts finely varied with concentric semicircles of black, ash-colour, and white: coverts of the tail barred black and white: tail cinereous, edged with white: breast and belly white; the first spotted with black: legs dusky green: toes bordered with a narrow finely-scolloped membrane.

Br. Mus. Lev. Mus.

Description.

SIZE of the Purre: length feven inches and a half: weight two ounces. Bill brown: irides hazel: the plumage on the upper parts very gloffy: the head brown, streaked with black: over each eye a white streak: neck dull ash-colour: back and wings greenish brown, crossed with dusky narrow lines: the breast and under parts white: quills brown; the first plain; on the nine following a white spot on the inner web: tail rounded, of a greenish glossy brown; the four middle feathers crossed with sine blackish lines; the two next on each side the same, with the tips white; the last but one spotted white on the edges; and the outer one white, marked on the inner web with brown bars: legs greenish brown.

PLACE AND
MANNERS.

This species is not uncommon with us in the summer season,

but

^{*} Ard. Zool. † Scopoli adds, that the toes are semipalmated.

but none are feen late in autumn. They breed with us, and the eggs are five in number; the female lays them in fome convenient hole in the bank of the river which she frequents: the colour of them dirty yellowish white, with numerous dusky markings, mostly round; and a few large ones of a paler colour, most at the large end. The bird is known at some distance by its piping note, which it frequently emits, and often flirts up its tail.

It is frequently met with also in France, into which it comes in May, and departs in September. It is also found in the northern latitudes of Sibiria, as far as Kamtschatka; and is also not uncommon in America, inhabiting Chateaux Bay to the north. The American species differs very little, except in the colour of the legs, which are yellowish.

One of these, which came under my inspection from Cayenne, had sewer spots on the back: a white bar across the wings: quills and tail brown: beneath wholly white, except here and there a little dusky mottling on the breast: the legs very pale.

► SPOTTED S.

ENGTH near eight inches: fize of a Thrush. Bill dusky, towards the base reddish: over the eye a white streak: the upper parts of the bird greenish brown: head marked with small longish dusky spots: these increase on the neck to the back, where they are much larger: the rump plain: the shoulders and wings marked with the same colour; but the spots are transverse:

DESCRIPTION.

A a 2

the

the under fide of the body is white, marked with dufky fpots: the two middle tail feathers greenish brown; the others white, croffed with dufky lines: legs dufky flesh-colour.

FEMALE.

The female differs in not having the under parts of the body fpotted.

PLACE AND MANNERS.

This species inhabits America, from Pensylvania to Hudson's Bay, where it arrives in May; and after breeding there, departs again in September. Is known there by the name of Chechisha-shish. It has also been met with in England; the bird from whence Mr. Edwards took his figure and description being shot in Essex.

NEW YORK S.

New York Sandpiper, Art. Zool. No 387.

DESCRIPTION.

THE leffer wing coverts are dusky, edged with white: the back dusky; the edges of the feathers cinereous: secondaries the same: tail coverts barred black and white: under side of the neck and body white: the breast spotted with brown: sides beneath the wings streaked with the same: tail cinereous.

PLACE.

Inhabits the province of New York.

26. STREAKED S. Description. SIZE of the common Snipe. Bill one inch and a quarter long, dusky: head and neck white, marked with numerous longitudinal dusky streaks: back dusky, the feathers edged with white: scapulars dusky, margined and mottled with ferruginous: lower part of the back and tail dusky ash-colour: wing coverts ash-colour: quills dusky: upper tail coverts, and all the under parts, white: sides spotted with dusky: legs dusky, with a tinge of yellow.

PLACE.

Inhabits Sandwich Sound.

SIZE

SIZE uncertain. Bill short, stout, and a little swelling at the point; colour dusky brown, with a black tip: the upper part of the plumage cinereous, mottled on the sides of the neck with a paler colour, which comes forward on the breast: over the eye a streak of white: chin, under parts of the body, and upper tail coverts, white: quills and tail dusky: legs deep brown.

BOREAL S.
Description.

Inhabits King George's Sound.

PLACE.

SIZE uncertain. Bill black: upper part of the neck and body dusky black, the feathers edged with ferruginous: beneath cinereous white: bastard wing, quills, and tail, black: legs cinereous.

NEWFOUND-LAND S. Description.

Inhabits Newfoundland. From the drawings of Sir Joseph Banks.

PLACE.

Sanderling, Albin, iii. pl. 88.

Purre, Br. Zool. N° 206. pl. 71.—Arct. Zool. p. 390.

Lev. Mus.

Description.

ENGTH feven inches and a half. Bill one inch and a quarter, black: the head and hind part of the neck are pale ash-colour, streaked with dusky: from bill to eye a white line: back and wing coverts brownish ash-colour; greater coverts darker, tipped with white: fore part of the neck, breast, and belly, white; the first mixed with brown: tail cinereous; the two middle feathers darkest, the others edged with white: legs dusky green.

Place and Manners. This species is common to most parts of Europe; and, if the bird meant by Kolben, at the Cape of Good Hope: is also common in America, at New York; from thence as far as Jamaica, and other West India Islands, and Cayenne. It only frequents these kingdoms in winter; when they may be seen on the coasts in vast flocks, slying in large circles, alternately taking in the water and land: are shot sometimes in great numbers, and thought very good to eat. Formerly known by the name of Stints; in some parts called Ox-birds. I have much suspicion that these breed on the coasts of Kent, as I had some birds sent to me by Mr. Boys of Sandwich, shot at Romney in the month of August, which scarcely differed

differed from the description, except in having the margins of the feathers on the upper parts of a pale ferruginous colour.

L'Alouette de Mer à collier, Bris. Orn. v. p. 216. 11. pl. 19. fig. 2. Le Cincle, Bus. Ois. vii. p. 553.—Pl. Enl. 852. Lev. Mus.

30. Var. A.

Description.

ESS than the Purre: length fix inches and three quarters. Bill black: on the upper parts of the head, neck, and body, the feathers are dusky or black in the middle, with pale rusous or whitish margins: throat and fore part of the neck white, minutely dashed with brown down the shafts: breast and sides brown, edged with white: the rest of the under parts white: the wing coverts are grey brown, dashed down the shafts with a deeper colour, the edges pale; some of the greater ones white at the tips: the quills brown; the nine first have the end half of the shafts white; the others more or less edged with white: the tail feathers are grey; the two middle ones brown on the inner webs; the others white within, and have the shafts white: the legs are brown.

This bird has much affinity with the *Purre*, and is often found in company with that bird: probably a fexual difference, or that of age.

Tringa ruficollis, Pall. Tr. iii. p. 700.

SIZE of the *Purre*. The bill is shorter than the head: the crown and hind part of the neck striated ferruginous and black: fore part of the neck, as far as the breast, deep ferruginous: the rest not unlike the *Purre*: legs black.

RED-NECKED P. S. Description.

This

SANDPIPER.

PLACE.

This is pretty common about the falt lakes of the province of *Dauria*, in fpring. It is gregarious, and often found in company with other species.

Br. Mus. Lev. Mus.

SIZE of the Jack Snipe. Bill black, rather fwelling out at the end: the upper parts of the plumage ferruginous, marked with large fpots of black, and a little white: wing coverts brownish ash-colour: throat, fore part of the neck, and breast, white, streaked with dusky: belly, thighs, and vent, white; the first irregularly marked with black in the middle: the tail has the two middle feathers brown, marked with rusous; the others very pale brown: legs black: toes divided to their origin.

PLACE AND MANNERS.

This species inhabits the northern parts of England: has been met with on the Yorkshire coast, and on the shores of Flintshire, both in May and August*. Said to lay four dirty white eggs, blotched with brown round the thicker end; with a few lesser ones at the smaller. It is also found in Greenland, Iceland, Scandinavia, the alps of Sibiria; and in its migration the coasts of the Caspian Sea.

34. RED S. Tringa Icelandica, Lin. Syft. i. Addend,
Tringa ferruginea, Brun. Nº 180.—Muller, Nº 203.
Scolopax subarquata, N. C. Petr. xix. p. 471. t. 18.
Red Sandpiper, Br. Zool. ii. Nº 202. pl. 72.—Arct. Zool. Nº 392.
Aberdeen D°, Br. Zool. 203.

DESCRIPTION.

ENGTH from eight to ten inches. Bill brown, one inch and a half long, and a little bent downwards: head, hind part of the neck, and beginning of the back, dusky, marked with red: fore part of the neck and breast cinereous, mixed with rust-colour, and obscurely spotted with black: lesser wing coverts cinereous: quills dusky: secondaries tipped with white: the two middle tail feathers dusky; the others cinereous: legs long and black.

Linnæus likens his bird to the Woodcock on the upper part; and fays, that the under parts are rufo-ferruginous: rump whitish, undulated with black: and that the shafts of the quills and tail feathers are white. The Aberdeen Sandpiper has the breast reddish brown, mixed with dusky: belly and vent white: else little differing in description from the Red, of which it is supposed to be the female, or a young bird.

PLACE AND MANNERS. The Red Sandpiper has appeared in great flocks on the coasts of Essex, on the estate of Col. Schutz: the Aberdeen one in Scotland. They have also been met with on the coasts of New York, Labrador, and Nootka Sound; and are also found in Iceland. In the summer frequent the neighbourhood of the Caspian Sea; also the river Don; but particularly about the mouth of the Choper. It is perpetually running up and down on the sandy banks, picking up insects and small worms, on which it feeds.

Lev.

Lev. Mus.

ENGTH eleven inches. Bill one inch and a half long, and black: crown of the head streaked with brown: the upper part of the neck, back, and wings, ash-colour, mottled with brown, and sparingly spotted with buff-colour, most numerous on the scapulars: throat, fore part of the neck, and breast, pale rusous: belly dirty white: rump the same, crossed with dusky bars: quills and tail dusky; the last palest: the upper tail coverts very long, almost reaching to the end of the tail: legs black.

35. SOUTHERN S. Description.

Inhabits Cayenne.

PLACE.

Tringa canutus, Lin. Syst. i. p. 251. 15.—Faun. Suec. 183.—Brun. Nº 182. Le Canut, Bris. Orn. v. p. 258. 21.—Bus. Ois. viii. p. 142. 36. KNOT.

The Knot, Raii Syn. p. 108. A. 5.—Will. Orn. p. 302. pl. 56.—Edw. pl. 276.—Br. Zool. ii. No 193.—Flor. Scot. p. 34. pl. 3.—Art. Zool. No 384.

Lev. Muf.

WEIGHT four ounces and a half: length nine inches, or more. Bill one inch and a quarter; colour dufky ash: irides hazel: from the bill to the eye a dufky line; over the eye a white one: the top of the head, neck, back, and wings, ash-colour: lower order of coverts tipped with white, and edged a little way up with the same, making a bar across the wing: greater quills darker, with white shafts: lower part of the back and tail coverts dark ash-colour, mixed with white, forming spots like crescents: tail ash-coloured: the under part, from the throat to the vent, white, with small dusky spots on the throat and breast: the sides under the wings, the belly, thighs, and vent,

Description,

croffed with dusky lines: ridge of the wing white: legs blueish ath-colour.

These birds vary. That in the British Zoology has the forehead, chin, and fore part of the neck, cinereous brown: back and scapulars brown; the feathers margined with ash-colour: tail ash-colour; the outer feather on each side white: toes divided to the bottom. We have also seen other inconsiderable varieties.

PLACE AND MANNERS.

These birds frequent the coasts of Lincolnshire in great numbers, and are caught in nets by means of Stale Birds; fourteen dozen have thus been taken at once *: the season, from August to November. In general disappear with the first frosts; yet Edwards's bird was bought in the London markets in the hard frost 1740, which did not commence till Christmas 1739. Are satted as the Ruffs, and are by some even preferred to those birds †.

This species has also been observed about Lake Baikal; and Mr. Pennant mentions a specimen which came from New York.

TURNSTONE.

Lev. Mus.

DESCRIPTION.

SIZE of a Thrush: length eight inches and a quarter. Bill nearly one inch; colour black, and turns a trifle upwards:

* Br. Zool. † They were fatted with bread and milk. Willughby. forehead,

forehead, throat, and belly, white: breaft black: neck furrounded with a black collar; from thence another bounds the fides of the neck, and passes over the forehead: head and lower part of the neck behind white; the first streaked with dusky lines: back ferruginous mixed with black: coverts of the tail white, crossed with a black bar: tail black; tipped with white: coverts of the wings cinereous brown; the lower order edged with white: primaries and secondaries black; the ends of the last white: tertials ferruginous and black: legs rather short, and of a full orange.

Male and female much alike.

In Edwards's bird the lower part of the back and rump are white. In that described by Willughby no mention is made of any white on the forehead or chin; and the middle of the back is white: yet in other things it scarcely differs.

These birds appear in flocks on the western shores of England, about Penzance and Cornwall, and Aberdaren in Merionethshire, three or four in company; also frequent on the shores of Norfolk, and in Shropshire. Are met with likewise in America. Appears in Hudson's Bay in May, and departs in September. Makes a slight nest on the dry ground, and lays four olive-coloured eggs, spotted with black, and hatches early. The young seen the middle of July. The natives call it Gega-washue.

The name of *Turnstone* has arisen from the method of searching for insects, by turning up the stones they lurk under with their bills, which are stout for that purpose.

PLACE AND MANNERS.

190

37. VAR. A. Tringa morinella, Lin. Syst. i. p. 249. 6. Le Coulon-chaud cendré, Bris. Orn. v. p. 137. 2. pl. 11. fig. 2. Turnstone, or Sea Dotterel, Catest. Car. pl. 72.—Br. Zool. ii. No 199.

DESCRIPTION.

SIZE of the other. The upper part of the head and neck, back, wings, and scapulars, are greyish brown; the seathers of the last pale on the edges: two of the scapulars white: forehead, chin, and throat, white: fore part of the neck and breast deep brown, variegated with white on the sides: lower part of the back, rump, belly, thighs, and under the tail, white: upper tail coverts part white, part brown: quills brown, with white shafts; some of them edged with white; and the base of all, from the fourth, white; increasing to the nineteenth, which, with the rest, is wholly white: the tail, half way from the base, is white; the two middle feathers brown from thence to the end, with the tips white; the four on each side the same, but the brown part narrower, as the feathers are more outward; the exterior feather wholly white, except a brown spot on the inner web: legs red.

The last described is most certainly a mere variety of the others. The sew which I have seen seem to vary much: hence the disagreement of the authors who have described them,

PLACE.

The above is found in Scotland, and its islands, as well as in North America.

VAR. B.

Coulon-chaud de Cayenne, Pl. Enl. 340.

DESCRIPTION.

BILL formed as in the others; colour dull yellow; tip black: plumage on all the upper parts mottled brown and white; the patches largest on the back: chin, throat, fore part of the neck,

neck, and all the under parts, white: on the wings a bar of white obliquely placed, and a fecond across the greater coverts: the prime quills and tail dusky black: secondaries edged with white: legs red.

Coulon-chaud gris de Cayenne, Pl. Enl. 857.

VAR. C.

BILL black: upper parts not much unlike the last: sides of the head mixed with more white: under the eye a dusky streak: forehead, chin, and throat, nearly white: breast mottled with smaller spots: from thence all the under parts are white: wings and tail as in the other; the margins and tips of the last white: legs dusky.

Description.

Both the above are described from the *Planches Enluminées*. Whether the bases of the quills and tail are white, cannot be ascertained. Both inhabit *Cayenne*; and it is very probable that they are mere varieties of the *Turnstone* first described.

BILL strait, for the most part not longer than the head*. Nostrils linear.

Toes three in number, all placed forwards.

[•] The long-legged, N° 3, is an exception, as the bill is nearly of twice that length. The two last species likewise differ in the bills, being curved at the end.

The birds of this genus feem to run much into one another in respect to plumage, so as to make it quite uncertain where to draw the specific line; and we are persuaded that, on a further investigation of the individuals, many which are here placed as distinct, will turn out to be varieties only.

Br. Muf. Lev. Muf.

LENGTH ten inches and a half. Bill one inch, dusky: irides dull red: the upper part of the plumage dusky, spotted with greenish yellow: round the eyes and the chin almost white: sides of the head, the neck, and sides of the body, the same as the upper parts, but much paler: middle of the belly dusky white: the greater quills are dusky: tail barred dusky and dull yellow: legs black.

Individuals of this species vary in colour: in some the belly is black, in others black and white; and the small claw is sometimes observed in lieu of an hind toe.

The male and female differ very little. In young birds the spots are not of a full yellow colour, inclining more to grey.

This elegant species inhabits *England* the whole year, and breeds on several of our unfrequented mountains: is very com-Vol. III. C c mon Description.

PLACE.

mon on those of the Isle of Rum, and the lostier Hebrides*. Also on the Grampian, and all the heathy hills of the islands and highlands of Scotland †. They make a shrill whistling noise, and may be inticed within gun-shot by a skilful imitator of their voice. The eggs are four in number, two inches and one eighth in length, more pointed in shape than those of the Lapwing; of a pale cinereous olive, blotched with blackish spots. On the continent they are met with in Sweden, Denmark, Lapland, Iceland, and other northern parts: to the fouth as far as Aleppo ‡; and, if the species be not mistaken, in the island of Batavia §, as well as in China: our last voyagers met with them at Owbybee ||, and York Islands, in the South Seas, but of a smaller size.

In America met with on the coast of Labrador, and Hudson's Bay ¶; from thence to New York, as low as Carolina; migrating from one to the other according to the seasons: and, if the sollowing be admitted as a variety, at the island of Saint Domingo, and in Cayenne**.

Br. Muf. Lev. Muf.

THIS is a fingular bird, on account of its great length of legs: it measures, from the end of the bill to that of the tail,

Description:

thirteen inches, but to the claws nearly one foot and a half. The bill is two inches and a half long, slender, and black: irides red: the forehead, round the eye, and all the under parts, are white: the crown of the head, back, and wings, glossy black: the hind part of the neck marked with dusky spots: rump white: tail the same, inclining to grey; the outer feather quite white: legs red: the outer and middle toes connected at the base.

PLACE.

This is now and then met with in England, but is far from common. Sir R. Sibbald mentions two being that in Scotland; the British Zoology, one killed near Oxford; and Mr. White of Fleet-street is in possession of another, which was shot out of a slock of six or seven, in Frencham ponds, in Hampshire. The plumage of this bird was wholly white, except the wings, and the back as far as the rump, which are black: bill and legs as the other. We believe this to differ in sex merely; the more so, as two birds, answering to the above descriptions, are placed in the Leverian Museum as male and semale.

It is common in Egypt, and is found in the marshes there in October; the food said to be chiefly flies. It is likewise plentiful about the salt lakes, and often on the shores of the Caspian sea, as well as the rivers which empty themselves into it; and in the southern desarts of Independent Tartary: we have also seen it in Chinese paintings; and it is known to be at Madras, in the East Indies*.

In the warmer parts of America it is sufficiently plentiful; and is seen as far north as Connecticut. We have received it from Jamaica, where Sloane tells us it is not uncommon. The spe-

cimens

^{*} Ray .- It is there described under the name of Red-legged Crane.

cimens from this place, as well as those from the East Indies, differ, in having not only the crown, but all the hind part of the neck, black; and measure fifteen inches in length*.

Lev. Muf.

DESCRIPTION.

SIZE of the Golden Plover. Bill one inch long, and black: eyes large: irides brown: eyelids black: the plumage on all the upper parts is black, spotted with orange: at the base of the upper mandible the seathers are black: the forehead between the eyes white, which passes over each eye in a line, down the sides of the neck, to the breast, uniting to form a band of the same across the latter: all the fore parts of the neck, breast, and under parts, are likewise black, except where the white band crosses: the vent spotted with white: secondaries, quills, and tail, barred brown and black: legs black.

FEMALE.

The male differs in having the temples black; but in the female they are dufky or brown.

PLACE AND MANNERS.

This inhabits the northern parts of Europe, Sweden, Denmark, the Isle of Oeland*, Iceland, and Greenland. In the last it is found,

* Known there by the name of Alwargrim, and is faid to frequent the barren heaths.—Faun. Suec.

though

though not in plenty, in all the fouthern lakes, feeding on mollusca, and the buds of black-berried beath: it arrives in spring; and after breeding retires southward. It is also sound in all the arctic parts of Russia and Sibiria. In America, at Hudson's Bay, it is well known by the name of Hawk's Eye. Comes to New York in May; breeds there, departing in collected flocks the end of October. It is probably met with also in Guiana, where Bancrost says it is seen in vast flocks near the mouths of rivers. The slesh is thought to be delicious.

6. ← NOISY PL.

SIZE of a Snipe: length nine inches and three quarters. Bill above an inch long, and black: eyelids red: eyes black: the forehead is white: between the eyes, across the head, a bar of black, passing on each side to the hind head: the chin and fore part of the neck is white; at the lower part of the neck the white encircles it like a ring, and is accompanied by a bar of black all round: on the breast is another black bar; and, except these, all the under parts are white: the hind part of the head, neck, and upper part of the body and wings, are dusky brown: rump rusty orange; the seathers very long: some of the seathers which fall over the greater quills fringed with white; the last black; a few of the outer ones have white shafts: tail the colour of the rump.

DESCRIPTION.

rump, much rounded in shape; near the end barred with black; the tip white: legs pale yellow.

Male and female much alike.

PLACE AND MANNERS.

This species is confined to America; and is found at New York, Virginia, and Carolina: remains in Virginia throughout the year; is there called Kill-deer, from the note resembling that word. Migrates to New York in spring, where it breeds, and lays three or four eggs: returns south in autumn.

This is a very clamorous, restless species; and, like the Jay in England, sets up its cry the moment any one approaches, to the entire disappointment of those who carry a gun.

Ringed Plover, Br. Zool. Nº 211.—Art. Zool. Nº 401.
Br. Mus. Lev. Mus.

DESCRIPTION,

ENGTH from fix to feven inches and upwards. Bill orange, the end half black: irides hazel: the base of the upper Vol. III.

Dd mandible,

mandible, and from thence through the eyes, and behind them to the ears, black: forehead white: behind this, from eye to eye, black: the rest of the head pale brown: chin and throat white, passing round the neck in a broad collar: beneath this, on the lower part of the neck, is a fecond of black, encircling the neck behind, but growing narrow as it passes backward: breast and all the under parts white: back and wing coverts pale brown: quills dufky, mixed with fome white on the inner webs: the two middle feathers of the tail greyish brown, growing almost black towards the ends: the three next on each fide the fame, with the tips white; the last but one is white, with a brown band: the outer one white, marked with a fpot only: legs orange-colour: claws black.

MALE.

In the male the white on the forehead takes up more space than in the female, there is a greater portion of white in the wings, and the plumage inclines more to ash-colour.

PLACE AND MANNERS.

These birds migrate into England in the spring, and depart in autumn: frequent our shores during the summer. They lay four eggs, an inch and a half in length, of a pale ash-colour, spotted and blotched with black, least so at the small end: these they lay on the ground, under some shelter, but make no nest. They run very fast, sometimes taking short slights, twittering loud at the same time, then alight and run again, and if much disturbed, either fly quite off, or creep into some hole till the danger is over.

Found also in several parts of the continent, and in Greenland, as well as in various parts of America, in the fouthern as well as the northern extremes. Visits Hudson's Bay the middle of June, and departs in September. Has the same manners there as in England.

England. Is a folitary bird; and observed, on any one's approaching near the nest, to use many stratagems to decoy the person from it, by drawing off his attention. Called at Hudson's Bay, Kisqua the napi shish.

SIZE of the last: length six inches and a half. Bill black: forehead, and before as far as the breast, white, passing round the lower part of the neck as a collar: the rest of the plumage pale dusky ash-colour: the end half of the tail dusky black, the tip fringed with rusous: legs pale.

8.

VAR. A.

DESCRIPTION.

Inhabits Cayenne. I have also seen this pale-coloured variety brought from Owbybee, and have one of the same which came from Hudson's Bay. We believe it to be a variety only of the last; and seems to be at least as plentiful on the American continent as the dark-coloured one.

PLACE.

SIZE of a Lark. Bill black: forehead white, passing backwards in a streak over the eye: from the base of the bill a streak of black runs through the eye, and reaches behind to the ears: the top of the head, the back, and wings, brown: round the neck a collar of white*: belly white: the quills blackish grey; the first has a white shaft; from the sifth to the eighth each feather has an oblong white spot on the outer web: secondaries and larger coverts tipped with white: the four middle tail

DESCRIPTION.

* Briffon's bird has a black collar beneath the white one.

Dd2

feathers

feathers are dusky brown; the two next on each fide dirty white, tipped with brown; and the two exterior ones white*: shape of the tail much rounded: legs black.

PLACE.

Inhabits Egypt, on the canal of the Nile. Feeds on infects and small Frogs. Found also in the diocese of Drontheim, and Norway, and common about the salt lakes between the rivers Argun and Onon, but not observed elsewhere in the Russian dominions.

VAR. A.

Charadrius Ægyptius, Lin. Syft. i. p. 254. 4.—Hasselq. Iter. p. 256. 31.

VAR. A. Description.

SIZE of a Thrush. Irides black: from the forehead a line of white passes over the eye to the hind head: the crown, sides of the head, and middle of the back, black: on the breast a band of black, passing backwards, and ending in a point on the back: breast, sides of the belly, thighs, and vent, yellowish white: throat and middle of the belly white: sides of the back and shoulders hoary: quills white, crossed with a band of black in the middle and tip: tail even at the end; colour of the feathers hoary; near the ends a bar of black, the tips white: legs blue: claws black.

PLACE.

Inhabits the funny plains of Egypt, and feeds on infects.

VAR. B.

Description.

Lev. Muss.

ENGTH eleven inches and a half. Bill half black, half orange: crown black: over the eyes a white streak, passing

* The eight middle feathers are brown, blackish near the ends, and white at the tips; the two outer ones white: on the outer web of the exterior feather a brown spot, and on the inner web of the last but one a few dusky spots.—Brisson.

on each fide backwards to the hind head as a wreath; this is again bounded by black: all the upper parts pale brown: chin white: fore part of the neck dusky white: on the breast a bar of black: belly and vent white: quills dusky black; some of the inner ones have the margins white: tail white, crossed with a bar of black, an inch broad, near the end; the tip white: legs long and red.

In the Leverian Museum it is called the red-eyed Plover; one of these is also in the collection of Sir Joseph Banks, brought from the Cape of Good Hope. It is the opinion of some, that the five last described are mere varieties*; which we cannot absolutely deny; but, till the circumstance can be more fully ascertained, we have suffered them to stand as above. The following may, we think, safely be admitted as a further variety of the Alexandrine species.

Petit Pluvie à collier de L'isle de Luçon, Son. Voy. p. 84. t. 46.

VAR. C.

DESCRIPTION.

SIZE of the Alexandrine Plover. Bill black: irides yellow: on the forehead is a spot of white: from thence beyond the eye, and the sides, black; this last is bounded by a brown line, passing from behind one eye to the other across the head: the hind head and nape, back, and wings, brown, the colour of umber: tail black, tipped with white: the throat, fore part of the neck, and belly, white; which is continued on each side below the nape, so as nearly to surround the neck: below this is a collar of black, passing quite round the neck: legs blackish.

This bird is found in the marshy places of the isle of Lusonia, especially such as are enriched by the dung of cattle

PLACE AND MANNERS.

that feed there, which, by fertilifing the spot, perhaps may contribute to increase the produce of insects, which are its food.

NEW-ZEALAND DESCRIPTION. PL. LXXXIII.

TRIFLE bigger than the Ringed Plover: length eight Bill one inch long, red, with a black tip: irides blue grey: eye-lids red: the fore part of the head, taking in the eye, chin, and throat, black, passing backwards in a collar at the hind head; all the back part of the head, behind the eye, greenish ash-colour; these two colours divided by white: the plumage on the upper parts of the body the fame colour as the back of the head: quills and tail dusky: the last order of coverts white for some part of their length, forming a bar on the wing: the under parts of the body white: legs red.

PLACE.

Inhabits Queen Charlotte's Sound. Known there by the name of Doodoorna-attoo.

In the collection of Sir Joseph Banks.

GREGARIOUS

DESCRIPTION.

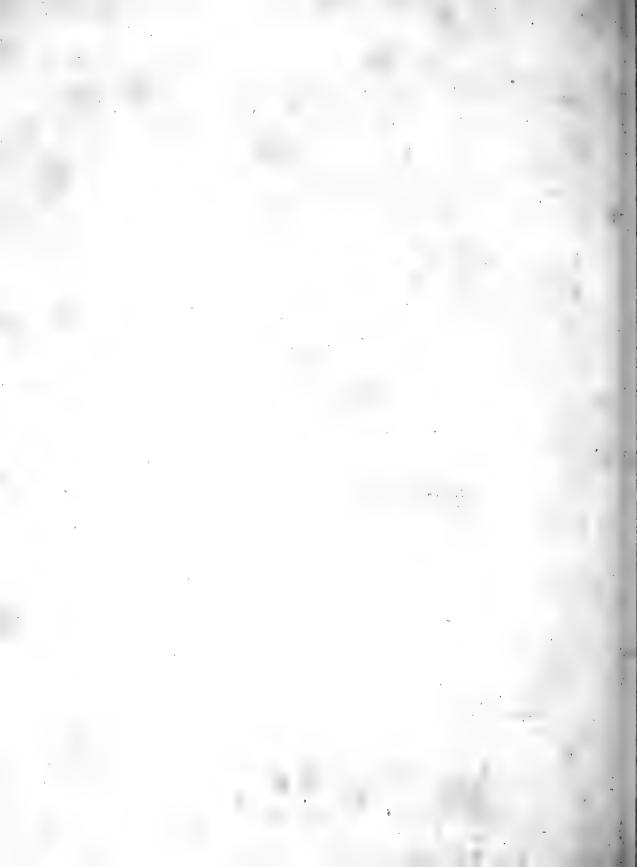

Charadrius Gregarius, Pall. Trav. i. p. 456.

SIZE of a Lapwing. Bill in shape and size the same as in that bird: crown of the head brown, mottled with white: forehead white, paffing in a streak over each eye to the hind head: through the eyes a black streak: body ash-colour, somewhat approaching to that of a Turtle: the chin whitish: at the lower part of the breast a large crescent of black; behind it a dirty rufous one; from thence to the vent white: tail even at the end, white, croffed with a black band, which is not confpi-

cuous

C New-Zealand Plover

cuous in the fide feathers: legs furnished with an impersect back toe.

This frequents the fields about the Volga, Jaick, and Samara, in flocks, and is pretty plentiful; but not feen farther north than 54 degrees. Is called by some the Hen of the Steppes*.

PLACE.

Charadrius Afiaticus, Pall. Trav. ii. p. 715.

ASIATIC PL.
Description.

A LITTLE bigger than the Ringed Plover. Bill as in that bird: crown of the head, the back, and wings, greyish ash-coloured brown: forehead, eye-brows, sides of the head, and chin, white: from thence to the middle of the neck ferruginous, bounded by a transverse band of brown: the rest of the under parts white: tail brown, the seathers whitish on the edges, and tipped with black: legs red.

Inhabits the falt lakes of the fouthern defarts of Tartary; and is a rare and folitary bird.

PLACE.

Charadrius Mongolus, Pall. Tr. iii. p. 700. 29.

MONGOLIAN PL.
Description.

SIZE of the *Dotterel*. Forehead white; crown black: from the bill arises a streak of black, which grows wider, and encircles the throat, which is white; beyond this the fore part of the neck is ferruginous: breast the same, but paler: belly white: back cinereous brown.

Inhabits the falt lakes on the confines of the Mongolian country, in tolerable plenty. Is a folitary species.

PLACE.

* Ruffia, vol. iv. p. 282 .- Dec. Ruff. ii. p. 17.

Lev. Mus.

DESCRIPTION.

Bill less than an inch long, and black: the forehead is dusky and grey mixed; the back part of it dull black: over the eye is a white band, which bends downwards, and passes to the hind head: sides of the head, and throat, white: the hind part of the neck, the back, and wings, greyish brown, the seathers margined with pale ferruginous; but those of the lower part of the back and rump incline to grey: fore part of the neck cinereous olive, mixed with a little white next the throat; the lower part of the neck is bounded with a line of black, beneath it another of white: the breast and sides of a pale dull orange: middle of the belly black; lower part of the belly and thighs rusous white: the greater quills are brown; the outer edge and shaft of the first white: tail olive brown; near the end a bar of dusky; the tip white; the two outer feathers margined with white: legs black.

FEMALE.

The female differs in being a trifle bigger; having the black on the belly mixed with white, and a white line on the breaft; the white over the eye narrower; and the colour in general more dull.

PLACE AND MANNERS. These birds are common in some parts of England; in others not known. Found in tolerable plenty in Cambridgeshire, Lincolnshire, and Derbyshire. Are migratory, appearing in flocks of eight

eight or ten, the latter end of April, and stay all May and June, when they get very fat, and are much esteemed for the table. In April and September taken on the Wiltsbire and Berksbire downs: in the beginning of the first month are seen on the sea side at Meales in Lancasbire, continuing there about three weeks; from thence remove northward to Leyton Haws, where they stay about a fortnight *; and at the same time are in plenty about Holderness, and upon the Yorksbire woulds †. It is very probable that they breed in the mountains of Cumberland and Westmoreland, as they appear there in May, and are not observed there after the breeding season ‡.

They are common in the northern parts of Europe, where we may suppose they likewise breed. Linnæus says, that they are very frequent in Dalecarlia, and the Lapland alps; and that they visit Sweden in May. Known to breed in the northern parts of Russia and Sibiria; appearing southward only in their migrations. They are stupid birds, and are easily enticed into a net, or destroyed by the gun.

PLACE.

Le Guignard d'Angleterre, Bris. Orn. v. p. 58.6. Dottrel, Albin, ii. pl. 63.

14. VAR. A.

THIS varies little from the last described. Irides white: the crown of the head varied with white, greyish brown, and pale yellow: fore part of the neck, breast, belly, sides, and thighs, pale yellow and white mixed: the two middle tail feathers brown; the others white: legs greenish.

^{*} Br. Zool. + Mr. Tunstall.

[‡] Ten or twelve were shot on the top of Skiddaw, in the month of June last. Dr. Heysham.—Breed on several of the Highland hills. Flor. Scot.

VAR. B.

DESCRIPTION.

Charadrius tataricus, Pall. Trav. ii. p. 714. 32.*

SIZE of a Missel Thrush. Top of the head black, the feathers edged with white: over the eye a white streak, passing to the hind head, where it is pretty broad: the hind part of the neck is dark ash-colour; the fore part the same, but paler: sides of the head and chin white, dotted with black: across the throat a transverse collar of black: the breast ferruginous, with a band of black; from thence to the vent white: wings brown; the edges of some of the seathers yellowish: tail feathers much the same, with the ends black.

PLACE.

Inhabits the falt lakes of the fouthern defarts of Tartary, with the last described.

BLACK-CROWNED PL.

.DESCRIPTION.

Black-crowned Plover, Art. Zool. No 402. Lev. Mus.

ENGTH ten inches. Bill an inch long, red, with the end black: forehead black: crown the fame, furrounded with a circle of white: throat white: neck and breaft very light ash-coloured brown, divided from the belly by a dusky transverse stroke: belly and vent white: back, scapulars, and wing coverts, cinereous brown: primaries dusky; towards the bottoms white: tail white at the base; black towards the end; the tip white: legs very long; naked an inch above the knees; and of a blood red: toes very short.

PLACE.

Inhabits the province of New York. Has much the habit of the European Dotterel.

BIGGER

PIGGER than a Snipe. Bill black: forehead pale reddish white: plumage on the upper part of the bird dusky; the feathers with pale edges: chin and fore part of the neck dusky white: lower part of the neck, breast, and under parts, dusky yellow oker-colour, with a tinge of red: the neck marked with pale and dusky streaks, and transversely mottled on the sides with narrow lines: quills dusky: legs blueish: claws black.

DUSKY PL.
Description.

Inhabits New Zealand. Found at Dufky Bay. The name given it by the natives Hapoho-èra. From the collection of Sir Joseph Banks.

PLACE.

ESS than the Lapwing: length twelve inches and a half. Bill dusky: irides blueish black: the plumage above, from the crown of the head to the rump, black; the feathers margined with fulvous yellow: the forehead and throat dusky white: breast fulvous, spotted with black: the rest of the under parts dusky white, spotted with black: the wing coverts are black, spotted with fulvous; the lower order brown black, tipped with white: quills brownish black; the shafts white: tail the same colour, crossed with whitish bands: legs blue: claws black, and blunt.

FULVOUS PL.
Description.

Inhabits the shores and marshy places of Otaheite. Communicated by Dr. Forster.

PLACE.

Lev. Muf.

ENGTH eight inches. Bill one inch, dark brown; the nostrils pervious: the plumage on the upper parts of the body brown; each feather margined with a golden yellow: the under part of the body white, except the breast, which is of a dusky

E e 2 pale

VAR. A.

DESCRIPTION.

pale brown: quills brown; the end half of the shafts white: the secondaries as long as the quills, and both of them reach to the end of the tail, and hide it: the tail is two inches long, brown, and marked with obscure pale brown spots on each side of the webs: legs about two inches long, and of a pale yellow.

PLACE.

Native place uncertain. It feems clearly to correspond with the last; but is considerably less in size.

WHITE-BEL-LIED PL. Descriptions

Lev. Mus.

ENGTH fix inches. Bill one inch: the plumage on the upper parts dirty brown: the forehead white: above and beneath the eye a streak of the same: under parts white: secondaries and prime quills equal in length; some of the first white from the base for half the length; the shafts white: six of the middle tail feathers brown; the outer of these is white just at the tip and base; the three exterior ones white; the last but one has a brown spot on the inner web near the tip; and the third is black at the end: legs pale blue.

PLACE.

Native place uncertain.

RED-NECKED PL.

DESCRIPTION.

SIZE of the *Purre*. The bill flesh-coloured; the end black: irides orange: head and neck black: on each side of the neck a large square chesnut spot, the size of a silver penny, almost meeting together at the back part: the upper part of the plumage ash-colour, with a little mixture of white about the bastard wing: the breast and under parts white: quills and tail dusky: legs slesh-colour.

PLACE.

Inhabits the South Seas. Found in Adventure Bay, Van Diemen's Land.

Charadrius.

Charadrius spinosus, Lin. Syst. i. p. 256. 12.—Hasselq. Iter. p. 260. 261.

Le Pluvier armé du Senegal, Bris. Orn. v. p. 86. pl. 7. sig. 2.—Pl. Enl. 801. SPUR-WINGED Le Pluvier à aigrette, Bus. Ois. viii. p. 99.

Br. Mus. Lev. Mus.

SIZE of the Golden Plover: length twelve inches. Bill above an inch long, and black: irides red: the crown of the head and throat are black, passing a little way down the neck before: the hind head a little crested: the back part of the neck, and upper part of the body, and scapulars, grey: sides of the head, and all the under part, from throat to vent, yellowish white, except a crescent of black on the breast, the convex part uppermost: the lesser wing coverts are black; the middle ones as the back; the greater yellowish white; but some of the outer ones, and the nine outer greater quills, are black; the ten next half white half black; the two following yellowish white; and the four next the body grey: on the fore part of the wing, just within the bend, is a spur half an inch in length, a little bent, and black: tail yellowish white, tipped with black, deepest on the two middle seathers: legs black.

This species inhabits the marshy places of lower Egypt, in the month of September; is also found in other parts of that neighbourhood. It goes there by the name of Dominican, the neck being black, with white sides, not unaptly resembling the same part of the habit of that order *.

* Hasselquist.

DESCRIPTION.

PLACE.

Charadrius

20. Var. A. Charadrius spinosus, Lin. Syst. i. p. 256. 12. B. Le Pluvier hupé de Perse, Bris. Orn. v. p. 84. 14.—Bus. Ois. viii. p. 98. Black-breasted Indian Plover, Edw. pl. 47. (male). Spur-winged Plover, Edw. pl. 280. (female).

DESCRIPTION.

ENGTH eleven inches and a half: breadth twenty-three inches: weight four ounces. Bill a little more than one inch, and black: top of the head gloffy black: hind head a little crefted: cheeks, hind head, and fides of the neck, white: upper part of the neck, back, fcapulars, rump, and upper tail coverts, chefnut brown: throat and fore part of the neck black: breaft and upper part of the belly the fame; the first gloffed with violet: the lower part of the belly and vent white: wing coverts like the back; but those farthest from the body, and secondaries, brownish chefnut, tipped with white: greater quills black: the tail four inches long; even at the end; white for two-thirds of the length; the rest black: legs deep brown.

FEMALE.

The other (supposed to be the female) is the size of a Lapwing. Bill and crest the same: it differs chiefly in having the whole of the neck white: the black on the throat only reaching for an inch down: breast and upper part of the belly black: outer tail seathers tipped with white. Both of them have a spur on the bend of the wing.

PLACE.

These inhabit Russia; and are very frequent near Aleppo, about the river Coic*.

* Russel, p. 72. pl. 11.—In the plate the bird seems to have a back toe, or at least a spur; though the text mentions only three toes in all. The having a minute spur is not uncommon in the Plover genus; the specimen in the British Museum is surnished with a small one.

6

Le Pluvier armé de Cayenne, Buf. Ois. viii. p. 102.-Pl. Enl. 833.

VAR. B.

Description.

ENGTH about nine inches. Bill one inch; colour dusky: the back part of the head, and nape of the neck, are white, mixed with grey: the fore part and sides black, passing back to the nape, and occupying all the hind part of the neck; and then comes forward on the fore part, above the breast: between this and the chin it is white: the middle of the back and wings is rusous grey: near the bend of the wing a sharp bent spur: scapulars and quills black: the under parts, from the breast, white: the base half of the tail is white, the rest black: legs yellowish.

This inhabits Cayenne.

PLACE.

Le Pluvier coiffé, Buf. Ois. viii. p. 100.

- du Senegal, Pl. Enl. 834.

HOODED PL.

DESCRIPTION.

LENGTH ten inches and a half. Bill yellow, red towards the end, and black at the tip: the forehead covered with a carunculated yellow membrane, passing round the eyes: the head, and a little way on the neck, black: the hind head furnished with a few short pointed feathers, hanging like a small crest; under this the hind head is white: the upper parts of the body are rufous grey: all the under parts white, with a few dusky dashes down the fore part of the neck: the quills and end of the tail black; the last short: legs red.

This is found at Senegal.

PLACE.

WREATHED PL.

Le Pluvier couronne, Buf. Ois. viii. p. 1013 Pluvier du Cap de Bonne Esperance, Pl. Enl. 800.

Description.

THIS is twelve inches in length. The bill is reddish, towards the point dusky: the head even with the eye, and chin, are black: round the crown runs a list of white, encircling the head like a wreath: the hind part of the neck, and upper part of the body, are brown, with a gloss of greenish purple in some lights; this is likewise seen on the breast, which is marked with a few spots of black: the neck, as far as the breast, is grey: the belly white; as are the greater coverts: the tail white, with a broad band of black near the end: quills black: legs rust-colour.

PLACE.

This comes from the Cape of Good Hope.

WATTLED PL.

Le Pluvier à lambeaux, Buf. Ois. viii. p. 102. Pluvier de la Cote de Malabar, Pl. Ens. 880.

DESCRIPTION.

SIZE of the Golden Plover: length nine inches and a half. The bill is yellow: on the forehead a naked bare skin, hanging down in a pointed slap on each side of the jaw: crown of the head black: through the eye a white streak: the neck and upper parts of the body yellowish grey, deepest on the back: the under parts, from the breast, white: across the greater wing coverts a band of white: quills black: the tail is like the back, crossed with a black bar at the end; and the tips and outsides of some of the outer feathers white: legs pale yellow.

PLACE.

This is met with on the coast of Malabar.

Le Pluvian, Buf. Ois. viii. p. 104.—Pl. Enl. 918.

BLACK-HEAD-ED PL. Description.

ENGTH feven inches. Bill black; one inch long: the upper part of the head, taking in the eyes, is black: the forehead yellowish, passing over each eye in a broad streak: the hind part of the neck and back are black: the wings, rump, and tail, greyish ash-colour: the quills black, mottled with white on the outer part of the wing: all the tail feathers except the two middle ones marked with black near the ends; the very tips white: the under parts, from the chin, pale rusous, deepest on the breast, where it is mottled with transverse dusky markings; and towards the vent nearly white: legs cinereous grey: claws black.

Native place not mentioned.

Le Courvite, Buf. Ois. viii. p. 128 .- Pl. Enl. 795.

ENGTH ten inches. Bill three quarters of an inch; slender, bent at the tip, not unlike that of the *Pratincole*: plumage in general cream-colour, palest beneath: behind the eyes a patch of black; through them a pale streak, passing to the hind head, and dividing the black: quills black: tail the same as the upper parts, marked with black near the tip: legs yellowish white.

The above was killed in France: it was observed to run with great swiftness.

CREAM-CO-LOURED PL. Descriptions

PLACE.

SIZE of a Crow: length fixteen inches and a quarter: weight feventeen ounces. Bill above three inches in length; ftrait, compressed on the sides, and in old birds blunt at the end; the colour of it and the eye-lids orange: irides a glowing crimson: the head and neck are black, except a small spot of white under the eye-lid, and a crescent of the same across the throat: the lesser wing coverts, scapulars, and upper part of the back, are black: the middle coverts the same, tipped with white: the greater white: the quills are black, marked more or less with

DESCRIPTION.

white within: the lower part of the back, rump, breast, and under parts, are white: tail white half way from the base, the end half black: legs dirty red: claws black.

Birds have been feen with the end half of the bill black; and in others the white under the eye-lid and chin are both wanting: the last is also not unfrequently met with white, mottled with black.

PLACE AND MANNERS.

The Oister-catcher is pretty common in England; most so on the western shores; feeding on shell-fish, and in particular oisters and limpets. On observing any one of the first, which gapes wide enough for the infertion of its bill, it thrusts it in, and takes out the inhabitant: it will also force the limpets from their adhefion to the rocks with fufficient ease. In turn feeds on marine insects and worms. In winter we often see these birds in considerable flocks; but they do not depart from us. In the fummer are met with only in pairs, though chiefly in the neighbourhood of the fea or falt rivers. The female lays four or five eggs, on the bare ground, on the shore, above high-water mark: they are of a greenish grey, blotched with black. The young are faid to be hatched in about three weeks. These birds are pretty wild when in flocks, yet are easily brought up tame, if taken young : I have known them to be thus kept for a long time, frequenting the ponds and ditches during the day, attending the ducks and other poultry to shelter of nights, and not unfrequently to come up of themselves as the evening approaches. Are known in some parts of England by the name of Sea-Pie, or Olive.

This species seems a general inhabitant; being found in most parts of the old continent, and universally in the neighbourhood of the sea. It is also sufficiently plenty throughout America,

from

from New-York to the Bahama Islands*, as well as Cayenne and Surinam †. Dampier met with it on the coast of New Holland ‡, and Kæmpfer at Japan §; our late circumnavigators, at Van Diemen's Land, Terra del Fuego ||, and New Zealand **: but in the last-named places, as well as in some others ††, the plumage is wholly black.

Br. Muf. Lev. Muf.

ENGTH twelve inches: breadth fixteen: weight four ounces and a half. Bill an inch and three quarters; colour dufky black, at the base reddish: irides red: all the upper parts are olive brown; the middle of each feather black: the under parts, from the chin to the middle of the belly, ash-colour*: the lower belly, thighs, and vent, the same, with rusous edges: sides of the body transversely barred with black and white: quills dusky: under tail coverts white: tail short, and black; the tips of the two middle feathers ferruginous; the others the same on the margins: legs dusky red: toes long, and divided to the bottom.

This species is sufficiently common in this kingdom; but in the northern parts of it is only seen in winter.

The egg is more than an inch and a half in length; of a pale yellowish colour, marked all over with dusky brown spots, of nearly the same size, but irregular.

It is found chiefly on the edges of ponds and rivulets well furnished with cover, under which it may run for shelter on the ap-

* Brisson observes, that in some birds the feathers on the fore part of the neck are margined with white: such I have seen, but suppose them to be young birds.

TROGLODYTE R.
Description

SIZE of a small Fowl: length seventeen inches. Bill reddish brown, two inches long, and a trisle bent: irides dirty yellow: the feathers of the crown, neck, back, breast, and belly, are brown, margined with rusous grey: cheeks and throat cinereous: over the eye a streak of the same: the wings are very short; the coverts the same colour as the back: the bastard wing surnished with a spine, which is half an inch long, strait, pointed, and lies hid among the feathers: quills brown, marked with transverse ferruginous spots on each margin: vent and sides brown: tail four inches long; brown, margined with rusous grey: legs reddish brown.

That in the Leverian Museum has the upper parts of a deep chesnut, the seathers dashed with black down the shafts: the under parts cinereous, verging to chesnut on the breast: quills,

. Art. Zool.

lower

lower order of coverts, and tail, barred chefnut and black: legs flout, brown.

PLACE AND MANNERS.

These inhabit New Zealand, particularly in Dusky Bay, where they are numerous, and are called Water Hens; and indeed, at a distance, appear not unlike Fowls. They run swiftly, and scratch on the ground like our poultry: from the shortness of their wings are unable to fly, nor do they ever take to the water: chiesly met with on a sea-beach, and the skirts of woods, where they pick up worms, &c. their chief food. Are often found under the roots of trees; and will frequently run into holes, and hide under the bushes: said to cry against rain. Are very tame, insomuch as to suffer themselves to be knocked down with a stick. Were esteemed as good food by our people, but thought to be best when skinned: the sat is high-coloured, inclining to orange*.

They are found also in *Charlotte Sound*, and on the neighbouring islands, but in very small numbers.

PHILIPPINE R.

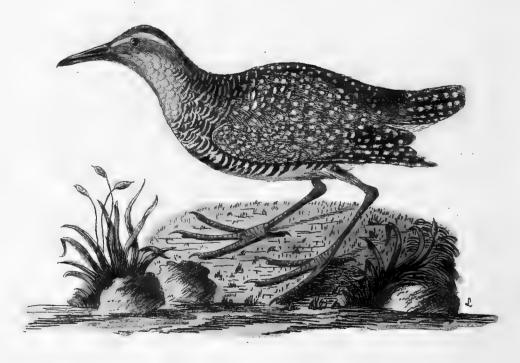

Rallus Philippensis, Lin. Syst. i. p. 263. 7. Le Râle des Philippines, Bris. Orn. v. p. 163. 4. pl. 14. fig. 1.—Pl. Enl. 774.

Le Tiklin, ou Râle des Philippines, Buf. Ois. viii. p. 160.

Description.

SIZE of the first species: length eleven inches. Bill thirteen lines and a half long; colour grey: the upper parts of the head, neck, and body, are dusky, the feathers edged with rusous grey; some of the scapulars spotted with white: over each eye a white streak, tending to the hind head; beneath this a broader

Philippine Rail. Var.A.

one, passing through the eyes backwards: throat dirty white: fore part of the neck rufous grey, marked with transverse indistinct brownish bands: breast, belly, sides, and thighs, barred grey and brown; least so on the belly, where it is almost white: wings marked with white and chefnut spots: greater coverts barred with chefnut: quills brown, the two first marked on the outer edge of each web with white, and towards the shaft with chefnut; the rest only with the last colour: tail dusky, edged with rufous grey; all but the two middle feathers spotted on the inner web with chefnut: legs grey.

Inhabits the Philippine islands, where it is called Tiklin.

Lev. Mul.

FENGTH ten inches. Bill an inch and a quarter, and brown: noftrils in a long furrow: the head and fides, taking in the eye and nape, ferruginous chefnut: from base of bill over the eye passes a pale streak almost to the hind head: the upper part of the body brown, but each feather marked with a black and white transverse stripe near the end, giving the appearance of black and white stripes on a brown ground: the hind part of the neck appears striated, but on the back more like spots, and more white than black: the rump is plain: the under parts from the chin, and down the middle to the breast, ash-colour; but the neck on the fides, the breaft and belly, are ftriated with black and white: vent pale ferruginous brown: the wing coverts not to be diftinguished in markings from the back: quills spotted brown and white: the tail is very little longer than the wings: the legs are flesh-colour: claws brown.

Inhabits Otabeite.

Hh

SIZE

RED-BREAST-DESCRIPTION.

SIZE of our Rail: length nine inches. Bill pale: plumage above dusky: over the eye a pale line: hind part and sides of the neck, and the breast, ferruginous: under parts of the body ash-colour; sides of it barred across with white narrow lines: legs yellow.

In the collection of M. Tunstall, Esquire.

CAPE R.

Rallus Capenfis, Lin. Syft. Mantiff. 1771. p. 525. The Rail, Brown Ill. p. 94. pl. 38?

DESCRIPTION.

TEARLY the fize of the Crake Gallinule. Bill black: head, neck, back, and upper part of the breaft, ferruginous: lower part of the breast, belly, thighs, and vent, quills and tail, undulated with black and white: two middle tail feathers ferruginous: legs of a deep blood red.

PLACE.

Inhabits the Cape of Good Hope; and, if the same as in Brown's work, also met with at Ceylon. The bill and legs in his plate are painted brown.

BLUE NECKED

DESCRIPTION.

I ENGTH seven inches and a half. Bill an inch and a half, colour red; the upper ridge and end dusky: all the upper parts of the head, neck, and body, reddish brown: chin, fore part of the neck, and breaft, pale blue: from thence to the vent white, transversely streaked on the sides with black, as in the common Water-Rail: vent white: legs red. . .

PLACE,

Inhabits the Cape of Good Hope. From the drawings of Sir Joseph Banks.

Rail,

Rail, Brown Ill. p. 96. pl. 37.

CEYLON R.

Description.

ARGER than the common Rail. Bill red: head dusky: neck, back, and tail, ferruginous; the last pretty long: wing coverts as the back: prime quills black: fore part of the neck, breast, and belly, reddish, clouded with brown: legs red.

Inhabits the island of Ceylon.

PLACE.

SIZE of ours. Bill blood red, tip pale brown: irides red: head brown: over the eyes a whitish streak: nape ferruginous: throat white: breast blueish ash-colour: back and rump black, sprinkled with small white spots, but not numerous: wings short, wholly of a deep black, variegated with interrupted white sasciae: quills brown: tail very short, black, spotted with white, scarcely to be distinguished from the rest of the feathers: belly, sides, and vent, whitish: legs slesh-colour: claws pale.

PACIFIC R.

Description:

Inhabits Otabeite, and the neighbouring isles.

PLACE.

I ENGTH fix inches and a half. Bill black: eyelids and irides red: general colour of the plumage brownish black: beneath dusky: legs reddish brown.

TABUAN R.
Description.

Inhabits Tongo Taboo*, Otaheite, and the neighbouring isles in the South Seas.

PLACE.

This varies in having the plumage more inclined to brown: the vent white, transversely barred with black lines: legs red. Inhabits the island of Tanna. Sir Joseph Banks.

· Cook's last Voy. i. 158.

Hh2

Br.

BLACK R.

Br. Mus.

DESCRIPTION.

SIZE of the Spotted Gallinule: length nine inches. Bill yellow at the base; the tip brown: general colour of the plumage dusky black, deepest on the head: legs brown; in some birds red.

PLACE.

Inhabits the Cape of Good Hope, and other parts of Africa.

SANDWICH R.
DESCRIPTION.

SIZE fmall. Bill dusky ash-colour: general colour of the plumage pale ferruginous; the feathers on the upper parts darkest in the middle: tail short, hid by the upper coverts: legs dusky slesh-colour.

PLACE.

Inhabits Sandwich Isles. Was also found on the island of Tanna*; but the plumage is darker on the upper parts; and the bill and legs yellowish. Sir Joseph Banks.

OTAHEITE R.
DESCRIPTION.

ENGTH fix inches. Bill three quarters of an inch, black: the head, neck, and all the under parts of the body, dark ash-colour; palest on the chin: the upper parts, and wing coverts, deep red brown: quills dusky, edged with white: edge of the wing, and the first quill feather, white: tail an inch and a half long, rounded in shape, and black: legs dusky yellow: claws black.

PLACE.

Inhabits Otaheite, and the Friendly Isles. Sir Joseph Banks.

* In Cook's last Voy. i. p. 151. mention is made of a sandy-coloured Plower at New Zealand: perhaps this species?

Lev.

Lev. Mus.

DUSKY R.
DESCRIPTION.

LENGTH fix inches. Bill fcarcely one inch; colour dufky black; edges of the mandibles yellowish: all the upper parts of the plumage deep brown, with a ferruginous tinge, and streaked with black: beneath ferruginous brown: legs two inches long, red brown.

Inhabits the Sandwich Islands.

PLACE.

Le Râle à long bec de Cayenne, Buf. Oif. viii. p. 163.—Pl. Enl. 849.

LARGER than our Rail: length nine inches and a half. Bill long in proportion, and rather stout; the colour of it ferruginous, with a dusky point: the upper parts of the body of a faint ash-colour, each feather dashed with a dusky streak down the middle: the chin is nearly white: from thence all the under parts are of a ferruginous white, striated on the sides of the body as in our Rail: legs pale straw-colour.

Inhabits Cayenne.

LONG-BILLED R. Description.

PLACE.

Le Râle tacheté de Cayenne, Buf. Ois. viii. p. 165.-Pl. Enl. 775.

LENGTH eleven inches. Bill one inch and a half, and yellowish: the back part of the head is dusky: the chin white: the rest of the head, neck, and body, spotted irregularly with black and white, and streaked transversely on the sides of the body, as in the common Rail: the wing coverts are brown dashed with white; the rest of the wing brown: tail dusky, some of the middle seathers edged with white: legs yellow.

Inhabits Cayenne.

VARIEGATED R. Descriptions

PLACE.

CAYENNE R.

Le Kiolo, Buf. Oif. viii. p. 164. Le Rafle de Cayenne, Pl. Enl. 368. Lev. Muf.

Description.

ENGTH near eight inches. The bill brown: the crown of the head is rufous: from thence all the upper parts are olive brown: beneath rufous as far as the thighs, which are the fame as the upper part: the vent pale: from the gape a broad blackish streak passing through the eyes, and beneath them: the quills are black: the legs reddish brown.

19. Var. A. Le Râle à ventre roux de Cayenne, Pl. Enl. 753.

Description.

THIS is only feven inches in length: and the upper parts are of a deeper brown: the crown chesnut; the chin and vent rusous white; and the broad streak through the eye is blue grey: the under parts are rusous, but much deeper than in the last bird, and that colour passes on to the vent and thighs; but the insides, and the lower parts of the last, are dusky. It is probable that this differs from the other only in sex.

PLACE.

Both these inhabit Cayenne. I have met with one of the last measuring very little more than six inches: they therefore differ much as to size.

These birds are common also at Guiana, where they are known by the name of Kiolo; arising, no doubt, from their cry, which is not unlike that word. These birds may be heard making a noise, or rather calling, in the evening just at sun-set, calling one another together, in order to pass the night; being dispersed singly among the thick bushes in the day-time. They make the

nest between the forks of the shrubs, near the ground, of a reddish kind of plant, making a cover at the top impenetrable to the rain.

JAMAICA R.

DESCRIPTION.

SIZE small: length fix inches. The bill is black, with the base reddish: head and throat black: the upper parts of the head, neck, and back, rusous brown, crossed with blackish streaks: fore part of the neck and breast blueish ash-colour: belly, sides, and thighs, barred white and brown: wing coverts brown, spotted with white: quills rusous brown, barred with black; the secondaries spotted with white: tail as the greater quills, marked with a few spots of white: legs brown.

Inhabits Jamaica, where it is called Bidi-Bidi.

PLACE.

Le petit Râle de Cayenne, Buf. Ois. viii. p. 167.—Pl. Enl. 847.

LITTLE R. DESCRIPTION.

THIS is the smallest of its race yet known: length five inches. The bill is brown: the upper parts of the body the same; darkest on the back and scapulars, which are streaked with white: the wing coverts black, spotted with white: sides of the body undulated black and white, as in our Rail: over the eye a streak of white: the under parts are pale dusky yellow, almost white on the chin and throat, and verging to ash-colour on the belly: quills brown: tail barred black and white: legs pale yellow.

Inhabits Cayenne.

PLACE-

21. + VAR. A.

Lev. Muf.

Description.

ENGTH five inches and a half. Bill brown; under mandible yellow: upper parts of the plumage brown, marked with many striated bands of white on the back and wing coverts: the chin and fore part of the neck, as far as the breast, dirty white: the middle of the neck behind rusous; sides of it ashcolour: belly, sides of the body, and vent, undulated black and white: quills and tail cinereous brown: legs yellow.

PLACE.

This last I received from Jamaica; and have also seen the same from Cayenne. It is clearly a mere variety or sexual difference from the Little Rail; and we have our suspicion also, that it does not essentially differ from the Jamaica species.

BARBARY R.

Barbary Water Hen, Shaw's Trav. p. 255.

DESCRIPTION.

LESS than a *Plover*. Bill an inch and a half long, and black: belly and breast dark brown, or rusty: back the same, but much darker: wings spotted with white: rump variegated above with black and white streaks, below white: legs dark brown.

PLACE.

Inhabits Barbary. From the length of bill, in proportion to the fize of the bird, and from no bareness of the forehead being mentioned, I suspect this rather to belong to the genus under which it is now placed, than to that of the Gallinule referred to by the author.

SIZE of the Water Rail: length nearly ten inches. Bill an inch and a quarter, and of an orange-colour: on the forehead is a membranous flap half an inch long, and nearly the fame in breadth; on each fide of the head is another of the fame, about a quarter Vol. III.

← CHESNUT J.

DESCRIPTION.

of an inch in breadth; and these together surround the base of the bill: the head, throat, neck, breast, and under parts, are black: in some the belly is mixed with white: back, wing coverts, and scapulars, fine chesnut; the outer angle of the wing mixed with black: on the shoulder a strong, sharp, yellow spine, a quarter of an inch in length: quills olive yellow, with the ends for one third, and the tips, margined with dusky; the outer one the whole way on the outer edge: tail rounded; the two middle feathers chesnut and brown mixed, with the ends black; the others the same, but no mixture of brown: the legs greenish ash-colour.

PIACE AND MANNERS. This species inhabits *Brasil*, *Guiana*, and *Surinam*; but is equally common at *St. Domingo*, where they frequent the marshy places, sides of ponds, and streams, and wade quite up to the thighs in the water. Generally seen in pairs, and when separated call each other continually, till they join again. Are very shy, and most common in the rainy seasons in *May* and *November*. Are at all times very noisy; their cry sharp and shrill, and may be heard a great way off. This, as well as the other species, is called by the *French*, *Chirurgien*. The sless is accounted pretty good.

— du Bresil, Pl. Enl. 846.

Spur-winged Water Hen, Edw. pl. 48.—Bancr. Guian. p. 173.

Br. Mus. Lev. Mus.

DESCRIPTION.

I ENGTH nine inches. Bill fourteen lines long, orange yellow: on the forehead a flap of red skin, laying back on the head, and divided at the hind part: crown of the head brown, marked with spots of a darker colour: hind part of the neck the fame, but very deep: above the eye a line of white, paffing down on each fide the neck; accompanying this a black one, which springs from the bill, and passes through the eye: sides of the head, throat, fore part of the neck, breaft, belly, thighs, and under tail coverts, white, with a few reddish spots on the sides of the belly and base of the thighs: on the fore part of the wing a yellow fpur: fcapulars pale brown: leffer wing coverts purplish chesnut; the middle ones brown; the greater black: the four quills next the body are brown; all the others green, margined with black at the ends; and the outer one the whole length, on the outer web: legs furnished with long toes as in all the others; colour of them blueish ash.

VARIETY.

One of these, which came under my inspection in a collection from Cayenne, was rather smaller: had the upper parts much paler:

paler: over the eye a streak of white, passing no further, and not accompanied by a black one: hind part of the neck dusky black: it had only a rudiment of a spur: and the red caruncle on the forehead was less, and laid back on the forehead. I conjecture this to differ either in sex or age from the other.

The species above-mentioned inhabits Brafil; and is said to be plentiful about Carthagena, in South America.

DESCRIPTION.

RATHER less than a Lapwing. Bill of a greyish colour, ffrait, and a little enlarged at the end: top of the head deep brown: over the eye a stripe of white, passing down on each fide the neck, and changing into pale yellow behind the eye: through the eye another stripe of an ash-colour accompanies the first quite down to the wing: the back is brown: the under parts, from chin to vent, white, except a large spot of brown on the breast: at the bend of the wing is a sharp spur: the lesser wing coverts are white, the others pale brown, transversely barred with black: the fecond quills white; the prime ones black: from the three last of these arise three naked shafts, two inches long, and ending in a launce-shaped feathered point; they spring from the middle of the fhaft of the feather to which they belong, the fhaft appearing as divided or branching into two at that part: the toes and claws are very long, as in the others, and of a dusky black.

This is found in the island of *Manilla*; chiefly frequenting the low moist places, borders of the sea, lakes, and rivers; and has the manners usual to others of this genus.

PLACE.

Br. Mul.

AFRICAN I. Pr. LXXXVII. DESCRIPTION.

TENGTH nine inches and a half. Bill dusky, of a pale brownish horn-colour at the tip: forehead bare: the upper parts of the plumage of a very pale cinnamon-colour: chin and throat white: breast of a tawny yellow, mottled and barred, on the fides of it and the neck, with black: the under parts from thence like the back, but darker: greater quills black: on the inner part of the bend of the wing a short blunt spur: through the eye, passing to the hind part of the neck, quite to the back, black: legs greenish black: toes and claws very long, as in the variable Jacana: hind claw an inch and a half in length.

PLACE.

Inhabits Africa.

CHINESE I. DESCRIPTION.

I.ENGTH twenty-one inches. Bill dusky: crown of the head, forehead, and all beneath, as far as the breaft, pale cinereous cream-colour: back part of the head black, of the neck yellow, divided from the white before by a line of black on each fide: the body vinaceous red: wing coverts white: quills black: tail long: legs and toes long, and of a greenish colour.

PLACE.

Supposed to inhabit China: feen by me among some fine drawings done in that country, and appears a very large species.

FAITHFUL I. DESCRIPTION.

Parra chavaria, Lin. Syft. i. p. 260. 5.

SIZE of a dungbill Cock, and stands a foot and a half from the ground. The bill is conic, a little bent, and of a dirty white colour; the upper mandible as in the Cock: nostrils oblong, pervious:

African Jacana!

vious: on both sides, at the base of the bill, is a red membrane, which extends to the temples; in the middle of this are placed the eyes: the irides are brown: the hind head is furnished with about a dozen blackish feathers, three inches in length, which form a crest; these hang downwards: the rest of the neck, which is pretty long, is covered with a thick black down; but under the bill and temples it is of a pure white: the body is brown: the wings and tail blackish, clouded with grey; the last short: on the bend of the wing two or three spurs half an inch in length: belly black, but less deep: the thighs are half way bare of seathers: knee joints thick and swelling: legs very long, strong, and of a yellowish red colour: toes also so long as to entangle the one in the other in walking.

This bird inhabits the lakes, &c. near the river Cinu, about thirty leagues from Carthagena, in South America, and is faid to feed on vegetables. Its gait is folemn and flow; but it flies eafily and fwiftly. It cannot run, unless affisted by the wings at the same time. When any part of the skin is touched by the hand a crackling is felt, though it is very downy beneath the feathers; and indeed this down adheres fo closely as to enable the bird at times to fwim. The voice is clear and loud, but far from agreeable. The natives, who keep poultry in great numbers, have one of these tame, which goes along with the flock about the neighbourhood to feed during the day, when this faithful shepherd defends them against birds of prey; being able, by means of the fpurs on the wings, to drive off birds as big as the Carrion Vulture, and even that bird itself. It is so far of the greatest use, as it never deferts the charge committed to its care, bringing them

PLACE AND MANNERS.

JACANA.

them all home safe at night. It is so tame as to suffer itself to be handled by a grown person; but will not permit children to attempt the same.—For the above account we are indebted to Linnaus, who seems to be the only one who has given any account of this wonderful bird.

Crake Gallinule, Br. Zool. Nº 216. pl. 75. - Art. Zool. Nº 412.

Br. Mus. Lev. Mus.

DESCRIPTION.

ENGTH nine inches and a half: weight from fix to eight ounces, Bill one inch, colour greyish brown: irides hazel: the plumage on the upper parts pale rusous brown, each feather dashed down the middle with black: the under parts the same, but paler, and not spotted: chin very pale: belly yellowish white: on the sides a few bars of the same: legs the colour of the bill.

PLACE AND MANNERS.

This is a very plentiful bird in some parts of these realms; particularly so in *Ireland*, where it is probable they pass the winter. Are also sound in most of the *Hebrides* and *Orknies*. Appear at *Anglesea* in *Wales* about the 20th of *April*; supposed to have come from *Ireland*. Few places in *England* are destitute of them in summer: are sound also in *Scotland* and the *Orknies**; but no where what may be called common; and it is said that wherever *Quails* are in plenty, the *Crake* abounds †; at least it is so observed in the temperate parts of *Russia* and *Sibiria*, where

^{*} Flora Scot.

⁺ Hence called the King of the Quails.

they are fufficiently common *. Are found on the continent as far as Norway: inhabit also Germany, France, Italy, and Greece; and are feen, if we mistake not the species, spring and autumn at Aleppo †; but only on their passage north and south. This bird is faid to lay ten or twelve eggs, an inch and a half in length, and not very unlike those of the Miffel Thrush, of a reddish cinereous white, marked with ferruginous blotches, with a few indiffinct ones of a pale reddish ash-colour: these it lays among the thickest grass, on a bed made of moss or dry grass. The young are covered with a black down, and very foon find the use of their legs. The old ones run fast, but fly awkwardly, with the legs hanging down. The usual note is not unlike the noise made by drawing one's nail over the teeth of a Comb; and is compared to the word Crek, Crek, Crek, which it often repeats; whence it is called in fome parts the Corn Crake. The food is grain and feeds of many kinds, as also insects. On their first arrival in England are so lean as to weigh less than fix ounces; but before their departure have been known to exceed eight, and are so fat that we have more than once feen it exude through the skin like oil, soon after the bird was killed. Their flesh is reckoned an exquisite morsel.

SIZE of the Crake Gallinule. Bill larger than in that bird, and black: the upper parts of the head, neck, and body, fine rufous brown: the under much paler: quills and tail darkeft: the chin and vent reddish white: legs dusky red.

I received this from Jamaica.

Particularly fo about the Steppes of Sysran, as well as other deserts, where they make a great noise of nights; and are known by the names of Dergun and Korastel. Dec. Russ. i. 470.

PLACE.

Inhabits Carthagena.

CAYENNE G.

La grande Poule-d'Eau de Cayenne, Buf. Ois. viii. p. 182.—Pl. Enl. 352.

Lev. Mus.

DESCRIPTION.

ENGTH eighteen inches. Bill yellow, with a dusky tip: the chin, sides of the head, and a little way on the fore part of the neck, greyish white: head, neck, tail, lower belly, and thighs, dusky grey brown: back and wing coverts dull olive: breast, upper part of the belly, and quills, bright reddish rusous colour: legs red.

The young birds are wholly grey, not having any red about them till after the first moult.

PLACE.

Inhabits Guiana and Cayenne, where it is pretty common in the marshy places, and lives on small fish and infects.

LENGTH

LENGTH seventeen inches. Bill two inches and a half; base red; end yellow: crown brown: hind part of the neck cinereous brown: back greenish brown: quills the same, with rufous margins: chin white: fore part of the neck and breast bright rusous: belly, thighs, vent, and rump, black: sides and under wing coverts transversely barred with rusous and black: legs red, and pretty long.

BLACK-BEL-LIED G. Description.

Supposed to inhabit Cayenne, as it was among others from that place.

PLACE.

La Poule-Sultane de Madrast, Bris. Orn. v. p. 543. 10. L'Angoli, Buf. Ois. viii. p. 205. Madras Rail-Hen, Raii Syn. p. 194. pl. 1. sig. 4.

MADRAS G.

SIZE of a Duck. The bill and legs pretty long: forehead bare and white *: the plumage on the upper parts of a fine ash-colour: sides of the head, and under parts, white: across the lower part of the neck black spots in the shape of crescents: quills ash-colour, edged with black: the tail is short.

DESCRIPTION:

Found in the neighbourhood of *Madras*, where it is called *Boollu-cory*. It is also at *Malabar*, and known there by the name of *Caunangoly*.

PLAGE.

• This is not mentioned in Ray's description, nor does it appear in the very bad figure in the plate.

Br. Mus. Lev. Mus.

DESCRIPTION.

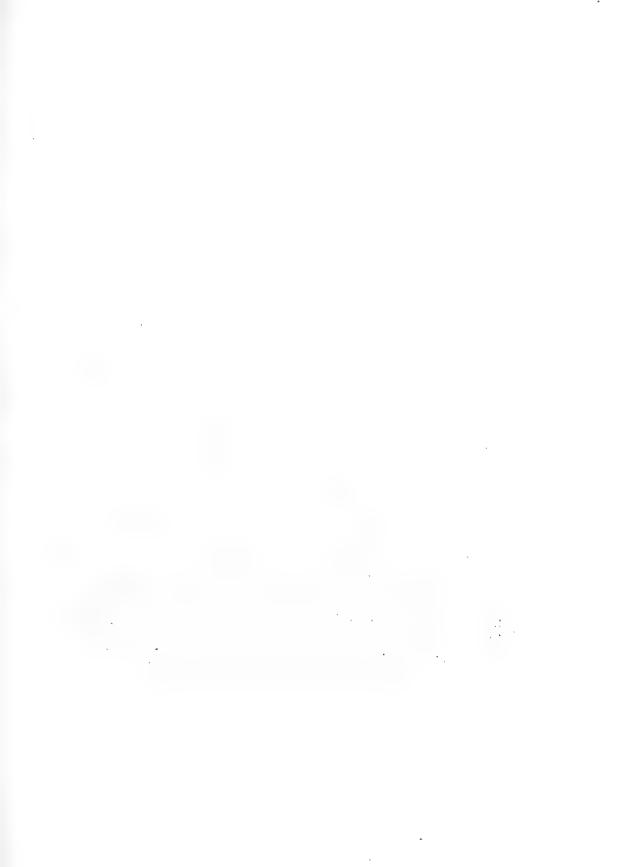

SIZE of a Fowl: length one foot five inches. Bill very ftout at the base, compressed on the sides, and above an inch and a half in length; colour a deep red: irides sulvous: the forehead bare and red: the head and hind part of the neck are glossy violet: cheeks, throat, and fore part of the neck, violet blue: back, rump, and scapulars, dull green, but glossy: quills the same, but brown within: the tail nearly the same, and rounded in shape: legs very stout, and the colour of the bill.

FEMALE.
PLACE AND
MANNERS.

The female is smaller than the male.

This bird is more or less common in all the warmer parts of the globe. On the coasts of Barbary they abound, as well as in some of the islands of the Mediterranean. In Sicily they are bred in plenty, and kept for their beauty; but whether indigenous there we are not certain. It is frequently met with in various parts of the south of Russia, and western parts of Sibiria, among reedy places; and in the neighbourhood of the Caspian Sea not uncommon: but in the cultivated rice-grounds of Ghilar in Persia, in great plenty and in high plumage. The female makes the nest among the reeds in the middle of March; lays three or four eggs, and sits from three to four weeks. That it is com-

Toes placed falfely, two before and two behind

Martinico Gallinule.

mon in China the paper-hangings from thence will every where testify. Is also met with in the East Indies, the islands of Java, Madagascar, and many others. Our late navigators saw them at Tongataboo in vast numbers, as well as in the island of Tanna*, and other parts. It is also common in the southern parts or America.

In respect to its manners, it is a very docile bird, being easily tamed +, and seeding with the poultry, scratching the ground with the foot as the Cock and Hen. It will seed on many things, such as fruit, roots of plants, and grain; but will eat fish with avidity, dipping them into the water before it swallows them: will frequently stand on one leg, and lift the food to its mouth with the other, like a Parrot. A pair of these, kept in an aviary in France, made a nest of small sticks, mixed with a quantity of straw, and laid six white eggs, perfectly round; but the hen was careless of them, and they came to nothing. The sless said to be exquisite in taste ‡.

LESS than the common Gallinule, and the body more slender: length about twelve inches. Bill thirteen lines long, yellow, with a red base: forehead bald and blue: irides red: the plu-

DESCRIPTION.

^{*} Forft. Voy. i. 448. ii. 358. - Cook's last Voy. i. 226. 334.

[†] In Dec. Ruff. ii. p. 240. this is denied; observing, that it will sooner lose its life than its liberty. ‡ Id.

mage is in general of a fine glossy green; but the head, neck, and under parts, are of a changeable blue: the vent white: quills and tail dusky, edged with green: legs yellow: toes very long, and slender. That described by Brisson differs from the above in having the bare part of the forehead and legs red; and is said to inhabit the East Indies as well as America.

PLACE AND MANNERS.

I have feen many of these birds, both from Cayenne and the West India Islands, all of which answered to our description, except one, which had the upper parts of the plumage blue green, tinged with brown: the crown of the head brown: beneath white; a little mottled with black in the middle of the belly, and greatly so across the lower part of the neck, just above the breast: chin quite white: legs brown. This seems by description to differ greatly; but on comparison of size, shape of bill, and legs, I am inclined to suppose it of a different sex only, if not a young bird.

These have been brought alive to *England*; but not so tame as to be at large. Such as have come under our inspection were content to live on *rice*, *bread*, *lettuce*, and other such food, and feemed to bear confinement tolerably well.

8. FAVOURITE G. La Favorite de Cayenne, Buf. Ois. viii. p. 207.—Pl. Enl. 897.

Lev. Mus.

DESCRIPTION.

ENGTH twelve inches. Bill yellow: upper parts of the plumage deep blue: fides of the head and neck paler: fore part of the neck blueish white: belly, thighs, and rump, white: quills and tail brown, the last darkest: legs long, yellow: hind toe very long.

PLACE.

Inhabits Cayenne.

Br. Mus. Lev. Mus.

DESCRIPTION.

weight fifteen ounces. Bill red, with a greenish tip; at the base of it a red bare membrane, spreading some way on the forehead: irides red: colour of the plumage sooty black above, with a tinge of olive; beneath cinereous: outer edge of the wing, and under tail coverts, white: above the knee, at the commencement of the bare part, a circle or garter of red: the rest of the bare space, and legs, are greenish: the toes stat and broad.

The female is less, the colours paler, and the throat sometimes * white.

PLACE AND MANNERS. This is a common species in England; frequenting every where the borders of rivers and ponds, where weeds grow. It makes a nest upon some low stump or shrub by the water side, composed of herbaceous matter; and lays seven eggs, almost two inches in length, of a yellowish white, marked with irregular reddish brown spots, which are not numerous; with a few minute ones interspersed; and breeds twice in the season. It slies awkwardly, with its legs hanging down, and not far at a time; though it runs pretty saft; and will now and then, notwithstand-

^{*} Not always; for in some it is only grey, and in others like the rest of the neck.

ing it is not web-footed, fwim, which it feems to do tolerably well.

It is pretty common on the continent, though in some parts more scarce than in others. Is also an inhabitant of America, from New York to Carolina; and is recorded as a native of Jamaica*, and other islands in the West Indies. Is said to feed on plants and small fish. The slesh is for the most part pretty good.

Red-tailed Water-Hen, Ind. Zool. p. 10. pl. 9. Rallus Phænicurus, Zool. Ind. p. 19. pl. 9. RED-TAILED G.

DESCRIPTION:

SIZE of the common Gallinule: length nine inches: weight feven ounces and a quarter. The bill yellowish green; at the base reddish: forehead bare, and sless-coloured: the plumage above is black: the forehead, round the eyes, and under parts, white: the quills black, marked with large spots of a blueish cast: the vent and tail ferruginous red: legs dirty green, tinged with red: toes long.

This species inhabits Ceylon, where it is pretty frequent, and called Kalu-kerenaka; and seems to be one of the kinds we so often see figured in Chinese paintings.

PLACE.

Lev. Mus.

Description.

HIS species is the size of a Quail, but stands higher on its legs: length from seven to eight inches. Bill an inch long, and yellow: over the forehead somewhat bare: irides red: the crown, and the upper parts of the bird, are dull brown, spotted with black: the whole face, round the bill, the chin, and part of the neck before, black: sides of the head, the neck, and breast, blueish ash-colour: belly and sides dusky white; the last transversely barred with black: the wing coverts are the colour of the back, but plain; scapulars edged with white: outer edge of the wing white: quills and tail brown: legs dusky green.

Place and Manners.

These inhabit Virginia, at certain seasons, in vast plenty. Burnaby * mentions catching one hundred dozen of Sorusses in one

night,

^{*} Burnab. Trav. p. 42, also p. 16.—He here calls them more delicious than the Ortolan.

night, by the Pamunky Indians in King William's Country. "The manner of taking these birds is remarkable. The Sorus is not known to be in Virginia, except for about six weeks from the latter end of September: at that time they are found in the marshes in prodigious numbers, feeding on the wild oats. At first they are exceeding lean, but in a short time grow so fat as to be unable to sly: in this state they lie upon the reeds, and the Indians go out in canoes, and knock them on the head with their paddles. They are rather bigger than a Lark, and are delicious eating. During the time of their continuing in season you meet with them at the tables of most of the Planters, breakfast, dinner, and supper."

DESCRIPTION.

length less than nine inches: breadth near fifteen: weight four ounces. The bill three quarters of an inch long, and of a greenish yellow: irides reddish hazel: the head is brown, dashed with black: over the eyes a streak of pale grey: hind part of the neck and sides cinereous brown, marked with small white spots: back and wing coverts olive brown, dashed with black, and spotted with white on the edges of the feathers: greater coverts blotched and barred with white: sides of the head, beneath the eyes, the chin, and fore part of the neck, pale grey, dotted with brown: breast brown, spotted with white: sides under the wings irregularly barred with white: belly cinereous and white mixed; down the middle dirty white: vent and under tail coverts yellowish white: legs pale green.

This

^{*} Willughby observes, that the tail when spread out is concave, and not even, as in other birds, and is a peculiar characteristic.

PLACE AND MANNERS.

This bird haunts the same places as the common Gallinule, but is not very frequent in this kingdom: we have not been able to trace it farther north than Cumberland, where it is known to breed*; and one of them, in company with its mate, was shot near Dartford in Kent, the farthest fouth we have heard of it. It is supposed to be migratory here as well as in France and Italy, where it is found early in spring, and is not uncommon. We likewise find it in the southern reedy grounds of Rusha, and the west of Sibiria+; but we believe no where so plentiful as the common species. It is a solitary bird, except in breeding-time; skulks among the rushes and reeds, and builds among the latter: the nest is composed of rushes matted together in form of a boat, like which it is as it were moored, by fastening one end to a reed, to prevent its being carried away by the water. The female lays feven or eight eggs; the young run as foon as hatched, and are wholly black. Buffon mentions one of this species that was kept tame, and was observed to stand in water for a long time together, if not disturbed: it was fed with bread and hempfeed t.

A species analogous to this, if not the same, is also found at *Hudson's Bay*; it is much smaller, measuring in length only eight inches, breadth sourteen, and weighs scarce three ounces; it comes there in *May*, and is seen in plenty along the coasts of the bay, and about rivers, brooks, and lakes. Lays ten or twelve white eggs, in a bush or grass: departs in *Ottober*. Known there by the name of *Paupakapatesew* §.

SPECKLED G.

La Poule-Sultane mouchetée, Bris. Orn. v. p. 536. 7. Matkneltzel, Matkern, Raii Syn. p. 109. 10.—Will. Orn. p. 304. pl. 56.

DESCRIPTION.

SIZE of the Crake Gallinule: length eleven inches. Bill of a dull yellow: forehead bare, and of the fame colour: the upper parts of the plumage rufous brown, marked with black and white spots on the wings: sides of the head, throat, and fore part of the neck, white: from thence to the vent brown: the two middle tail feathers are black, tipped with white; the others brown: legs grey.

PLACE.

This frequents the marshes of Germany. It is called Matknelt-zel, and Matkern.

20. YELLOW-LEGGED G.

La Poule-Sultane rousse, Bris. Orn. v. p. 534. 6. La Smirring, Buf. Ois. viii. p. 180. Gallinula ochropus major, Raii Syn. p. 115. 6. The Water-Hen, called Ochropus, Will. Orn. p. 316.

DESCRIPTION.

SIZE of the common Gallinule. Bill yellow, with the end black: edges of the eyelids faffron-colour: forehead bare, and of a pale yellow: the rest of the head, and upper parts of the bird, rusous, spotted with black: sides of the head and under parts white: lesser wing coverts spotted with dusky, and a little brown; the edges reddish near the tips; the outer greater ones the same; but those near the body white: quills black: tail rusous, spotted with black: legs of a pale yellow*.

PLACE.

Inhabits Germany, where it is called Schmirring.

There is a figure in Gefner, see Ic. 103.—Av. 507. but it seems to want the back toe.

La Poule-Sultane brune, Bris. Orn. v. p. 531. La Glout, Buf. Oif. viii. p. 181.

PIPING G.

THE bill in this species is black: the forehead bare, and of a yellowish green: the plumage on the upper parts brown: fides of the head, and under parts, white; and there is a little mixture of the fame on the wing coverts: quills and tail brown: legs yellowish grey: claws grey.

DESCRIPTION.

Inhabits Germany, and frequents the banks of rivers and ponds, like most of the genus. It is known about Strasburg by the name of Glutt, and has a shrill kind of note not unlike that of a fmall flute or fife.

PLACE AND MANNERS.

Br. Mus.

with white: body and wings greenish ash-colour; outer edge of the last pale: under parts of the body pale ash: middle of the

PLACE.

GENUS LXXVI. SHEATH-BILL*.

N° 1. White Sheath-bill.

BILL ftrong, thick, a little convex; the top of the upper mandible covered with a corneous fheath.

Nostrils small, just appearing beyond the sheath.

Tongue round above, flat beneath, and pointed at the end.

At the bend of the wing a blunt knob.

Legs flout, gallinaceous, bare a little way above the knee; toes edged with a thick membrane, the middle one connected to the outer as far as the first joint; claws channelled beneath.

WHITE SH.
PL. LXXXIX.
Description.

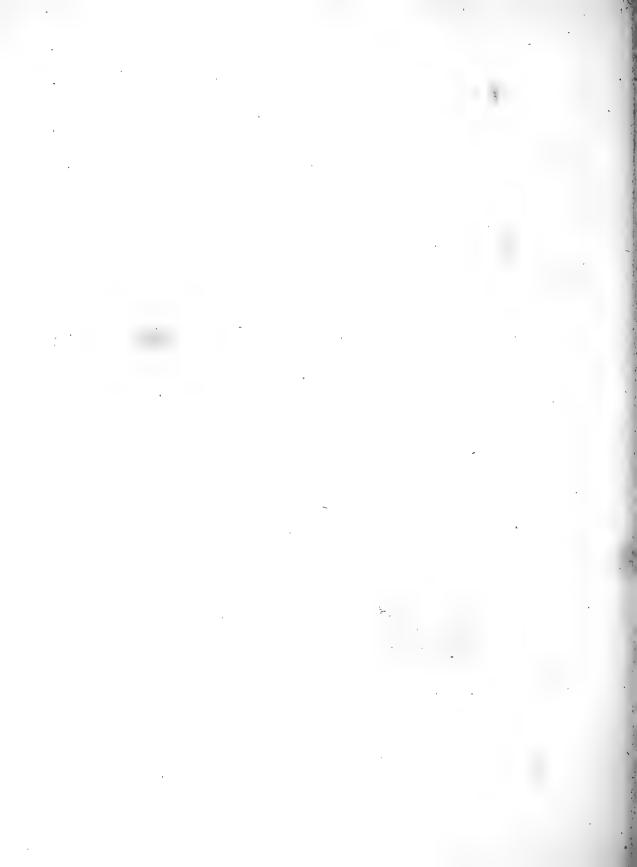

SIZE of a large Pigeon: length from fifteen to eighteen inches. Bill black at the base; over the nostrils a horny appendage, which covers them, except just on the fore part; and descends so low on each side, as to hang over part of the under mandible; this is moveable, and may be raised upwards, or depressed so as to lay slat on the bill: round the base, between that and the eyes, and round them, the parts are bare, and covered only with warty excrescences, of a white, or pale orange-colour; over the eye a brown or blackish one, larger than the rest: irides dull lead-colour: the plumage is all over as white as snow: at the bend of the wing is a blunt blackish knob: the legs are bare a little way above the knees, and are two inches long, stout,

· Genera of Birds, p. 43.

and

White Sheath-bill ?

and of a reddish colour: claws black. In young birds the tubercles round the eyes are very small, or wholly wanting.

These inhabit New Zealand, and several other parts explored by our late circumnavigators; and are apt to vary in regard to the colour of their extremities, as well as size, in the different places in which they have been seen. In those from Kerguelen's Land some had brown legs, with the toes black; and others the legs white, or a pale blue. In one met with at Staaten Land the legs were black; and the bill in some specimens of a pale brown.

These birds haunt the sea shores in slocks, and feed on Shell Fish and carrion*. In respect to their being used for food, our voyagers differ greatly: some of them put it in competition with the Duck†; while others tell us that it is worse than carrion; for it had such a horrid offensive smell, that they could not venture to taste the slesh, and that at a time when they were not easily disgusted‡: we may therefore venture to conclude, that those who praised it as a delicacy were at least very hungry.

DESCRIPTION.

BILL black, flatted near the tip: forehead white: crown dusky: hind part of the neck light grey: back, rump, and fcapulars, deep dove-colour, marked with dufky fpots; edges of the fcapulars yellow: coverts and prime quills dusky; the first edged with white: breast and belly white: tail dusky, edged with 9

with ash-colour: legs black: toes scalloped: the margins of the membranes finely ferrated.

In my collection is a specimen, which differs somewhat. The whole top of the head, sides, chin, and neck, are white: the hind part of the head and neck dusky: the prime quills plain; the secondaries margined with white: the scalloped membranes yellowish. I suspect it to be a young bird, not yet come to its full plumage.

Inhabits the northern parts of Europe, Iceland and Greenland; is feen also in England, but rarely. Frequent throughout Sibiria, in the neighbourhood of the lakes and rivers, especially in autumn. Also met with among the ice between Asia and America. If the same with that in the Philosophical Transactions, it frequents the salt marshes, and slies in slocks about the borders of the Caspian Sea.

VARIETY.

PLACE AND MANNERS.

Plain Phalarope, Ara. Zool. No 415.

BILL black, flender, dilated at the end: crown dufky and dull yellow: across each eye a black line: cheeks and fore part of the neck clay-colour: breast and belly white: back and tertials dusky, edged with dull yellow: wing coverts, primaries, and tail, cinereous; the last edged like the tertials: legs yellowish: toes bordered with a plain or unscalloped membrane.

Taken in the Frozen Sea, lat. 69½, long. 191½.

Nn2

Description.

as

as the crown, and covered with a white skin*: the head, neck, and back, are black; the last inclining to ash-colour: the breast, belly, and vent, ash-colour: outer edge of the wing white: at the beginning of the naked part above the knee a circle or garter of yellow: the colour of the legs yellowish green: toes furnished on each side with a scalloped broad membrane.

No difference observed between the sexes.

PLACE.

The Coot is pretty common throughout England at all feafons; fometimes met with many together in winter; but in breedingtime chiefly in pairs about the borders of ponds well covered with weeds, rushes, &c. and both swims and dives well. It makes a very large neft of weeds well matted together, lining it within with grass, &c. and lays as far as fourteen or fifteen eggs t, two inches and a quarter long, of a pale brownish white, regularly peppered with chocolate-coloured spots, some of them very minute, the biggest only an eighth of an inch in size, most spotted at the largest end: the young take to the water very soon after hatching. This species is not so numerous as might be expected; for we find that vast numbers fall a prey while young to the Buzzards, which frequent the marshes. The food is small fish and water insects; but will sometimes eat the roots of the bulrush, and with it feed the young; is faid likewise to eat grain. We believe this species to extend throughout the old continent, and perhaps the new also. Authors record it as inhabiting Greenland, Sweden, Norway, Russia, Sibiria, Persia, and China,

^{*} Brisson says red; but it is only so in the season of incubation. I have never yet seen it of a full red.

[†] As far as eighteen or twenty, Hist. des Ois.—And further, that if the first set taken away, it will lay ten or twelve more for a second hatch.

and many of the intermediate parts. It is also met with in famaica, Carolina, and other parts of North America. The Indians about Niagara dress their skins, and use them for pouches. Called in Carolina, Flusterers*.

A Coot has been once shot, at Spalding in Lincolnshire, which was white, except a few feathers in the wings and about the head +.

We do not find the *Coot* efteemed as food; but remember once to have tasted some young ones which were skinned and put into a pie, which was thought very good.

Fulica aterrima, Lin. Syft. i. p. 258. 3.—Scop. Ann. i. No 150.

Fulica major, or greater Coot, Raii Syn. p. 117. 2.—Will. Orn. p. 239-pl. 51.—Br. Zool. No 221.

THIS is of a larger fize than the last, but differs not in the colour of the plumage, except that it is blacker. Brisson distinguishes the two by the colours of the bare part of the forehead, which is in this white; and the garters, which are of a deep red ‡.

This bird is faid to be found in Lancashire and Scotland. It should feem to be a mere variety of the former, did not authors join in advancing the contrary. They are more plentiful on the continent, being found in Russia and the western part of Sibiria very common; and are also in plenty at Sologne and the neigh-

bouring

Vol. III. O o The

DESCRIPTION.

282

FEMALE.

The female is said to differ in having the head less tusted; in other things it much resembles the male *.

Young Birds.

The young birds differ exceedingly at different stages of life: at first they are perfectly downy, and striped, especially down the neck, with black: after this, when about half grown, the stripes on the neck are less distinct, being rather mottled than striped; and the under part, though white, is clouded with dusky †; at this period a sullness round the head is observed: as the bird advances still surther towards perfection the brown and white appear clear and distinct, the head becomes much tusted, and the horns are a little elongated. But we have great reason to believe that the bird does not obtain the sull and perfect crest till the second year at least.

PLACE AND MANNERS. The above are sufficiently common in some parts of England, breeding in the meres of Shropshire and Cheshire, and in the east fen of Lincolnshire, where they are called Gaunts; in some parts known by the name of Cargoose. The female lays four white eggs the size of those of a Pigeon: the nest is of a large size, and formed of bogbean, stalks of water-lilly, pond-weed, and water-violet, stoating independent among the reeds and slags; the water penetrates it, and the bird sits and hatches in that condition. The food of the old bird is small sish, which it gets by diving, and at times will eat vegetables. It feeds the young with small eels;

In one shewn to us at Mr. Boddam's as a female, the rust was white, and smaller than in the male: the tusts on the top of the head were shorter, and white also, the head having no rusous tinge about it.—We suspect the above to be a bird in incomplete plumage.

[†] See Brunnich, p. 42. Nº 139.

[†] Dr. Heysham mentions one of the Tippet Grebes being shot near Carlisse, which had half-digested wegetables, and a great number of feathers, in its stomach.

and will carry them, when tired, on its back: is feldom or never feen on land: is a quick diver, and difficult to be shot, as it darts down on the least appearance of danger; and seldom slies farther than the end of the lake it frequents *.

Colymbus urinator, Lin. Syst. i. p. 223. 9.—Scop. Ann. i. No 102 to La Grebe, Bris. Orn. vi. p. 34. 1. pl. 3. fig. 1.—Bust. Ois. viii. p. 227.— Pl. Enl. 941.

each

^{*} Br. Zool.

[†] Scopoli describes two birds: in one the upper parts are brown: belly and under side of the wings white. The other (supposed to be of a different sex) larger; but differs in having a white throat, a rusous neck, and two black streaks produced downwards from each eye.

each bird fells for about fourteen shillings *. It is also mentioned as a common bird in the lakes of Sibiria; but not seen in Russia +.

It is with some reluctance that we pen our doubts concerning the identity of this as a species, at least as being distinct from the great crested Grebe, in contradiction to what former authors have recorded on the subject. It is certain that the last-named bird varies exceedingly at different periods of life, from what has been faid above; and we are likewise as certain that the birds which have been pointed out to us as the Geneva Grebes, have been no other than young ones of the great crested, not having yet attained the crest; and whoever will compare Brisson's three figures of the birds in question 1, will find (the crest excepted) that they all exactly coincide, allowing for their different periods of age. We have been further led into this opinion from the circumstance of a large flock of them, which appeared in various parts of the shores of the Thames, from Gravesend to Greenwich, last winter, many of which were killed and came under our inspection: among them we found the greatest variety about the head, from being perfectly without a creft, to the most complete one, with all the intermediate stages above mentioned.

CAYENNE GR.

Le grand Grebe, Buf. Ois. viii. p. 242. Grebe de Cayenne, Pl. Enl. 404. fig. 1.

DESCRIPTION.

THIS is nineteen inches and a half in length. The bill is dusky; the under mandible yellow at the base: head, and upper parts of the neck and body, dusky brown: fore parts, as far

[•] Br. Zool. † Mr. Pennant. † Brif. vol. vi. pl. 3. fig. 1. pl. 4. and pl. 5. fig. 1. 6

as the breaft, and fides, rufous: the last mixed with brown: breast and upper part of the belly white; the lower part, and vent, brown: legs dusky.

Inhabits Cayenne.

PLACE.

Colymbus auritus, Lin. Syft. i. p. 222. 8.—Faun. Suec. 152.—Scop. Ann. i. Nº 100.—Brun. 136. 137.—Muller, p. 20.

Eared Dobchick, Edw. pl. 96. fig. 2.

---- Grebe, Br. Zool. Nº 224. pl. 79. -- Arct. Zool. p. 499. B. Br. Mus. Lev. Mus.

SIZE of a Teal: length twelve inches. Bill one inch, black; bending a little upwards at the point; the colour of the base reddish: lore and irides crimson: the head is very full of seathers, and of a dusky black: the neck and under parts of the body the same *: from behind each eye springs a tust of orange-coloured seathers, growing broader, and almost meeting behind: the breast and under parts are silvery white: sides of the body ferruginous chesnut: legs black.

FEMALE.

The female differs in having the head less full of feathers than the male.

PLACE.

This is found in the northern parts of Europe, the temperate and northern parts of Sibiria, and in Iceland. Said also by Bougainville to be met with in Falkland Islands, where it was named the Diver with Spettacles ‡.

[•] In some birds the fore part of the neck is mottled with white.

¹ See Boug. Voy. p. 61.

VAR. A.

La petite Grebe huppée, Bris. Orn. iii. pl. 3. fig. 2. Colymbus nigricans, Scop. Ann. i. N° 101? Ash-coloured Loon, Raii Syn. p. 124?—Will. Orn. p. 340. pl. 61?

DESCRIPTION.

ODY the fize of a Lapwing: length eleven inches. Bill an inch and a quarter, black: head rather full of feathers, and elongated into two fhort tufts, one on each fide the hind head: colour of the head, neck, and upper parts, fine brown: fides of the head, and fore part of the neck, white, the last marked with chesnut spots; the white of the throat passes far back below the hind head on each side, and under this the brown advances towards the fore part: the breast, belly, thighs, and sides, white; the last marked with chesnut and brown spots: wing coverts brown; some of those next the body, and part of the second quills, white: legs olive brown.

This feems to partake both of the last as well as of the following species; but we hesitate not to pronounce it the former in one of its progressive stages towards persection, as it varies much like the *crested species* at the different periods of age.

the same: forehead, and beneath, from chin to vent, white: breast very gloffy: at the throat the white passes backwards almost to the hind head, and the brown comes forward on each side on the middle of the neck: on the thighs a few black spots: legs sless-colour tinged with purple.

In fome birds the whole neck is ash-coloured; and others are spotted between the legs with black.

This species inhabits the fens of Lincolnshire. Mr. Edwards mentions his having had several out of the London markets, from which place we have likewise received a specimen.

PLACE.

Eared or Horned Dobchick, Edw. pl. 49. Horned Grebe, Art. Zool. No 417.

Lev. Mus.

6. HORNED GR.

Pr. XCI.

DESCRIPTION.

SIZE of a Teal: weight one pound: length one foot: breadth fixteen inches. Bill one inch, dusky: head very full of feathers, and of a glossy deep green, nearly black: through each eye a streak of yellow feathers, elongated into a tust as it passes to the hind head: upper part of the neck and back dusky brown: fore part of the neck and breast dark orange red: lesser wing coverts cinereous; the greater and quills black; middle ones white: belly glossy white: legs cinereous blue before, pale behind.

Inhabits Hudson's Bay. First appears in May, about the fresh waters. Lays from two to four white eggs, in June, among the aquatic plants; said to cover them when abroad. Retires south in autumn; appears then at New York, staying till spring, when it returns to the north. For its vast quickness in diving it is called the Water Witch. Known at Hudson's Bay by the name of Seekeep.

PLACE AND MANNERS.

6. Var. A. La petite Grebe cornue. Bris. Orn. vi. p. 50. 5.—Bus. Ois. viii. p. 237. Grebe d'Esclavonie, Pl. Enl. 404. fig. 2.

DESCRIPTION.

HE head of this bird is much tufted, and black: behind the eyes a stripe of loose rusous yellow feathers: the hind part of the neck, and upper parts of the body and wings, dusky black: on the quills a patch of white: fore parts, from the chin to the breast, and sides, chesnut: breast, belly, and thighs, resplendent white: legs lead-colour.

PLACE.

Said to inhabit Sclavonia, and feems to be a mere variety of the last species.

RED-NECKED GR. Le Grebe à joues grises, ou le Jougris, Buf. Ois. viii. p. 241.—Pl. Enl. 931. Red-necked Grebe, Arct. Zool. p. 499. C.

DESCRIPTION.

THE crown, hind part of the neck, back, and wings, are dusky brown: secondaries white: cheeks and throat the same; the first marked with a few brown streaks: under side of the neck bright ferruginous: belly white: legs dusky.

PLACE.

This species was sent to Mr. Pennant from Copenbagen, and supposed to inhabit Denmark or Norway; it is also found, though very rarely, towards the Caspian Sea. That mentioned by Buffon was seventeen inches in length; had the breast mottled with ferruginous; and a white spot on the quills: in other things it exactly coincided with the above description.

La Grebe de l'Isle de St. Thomas, Bris. Orn. vi. p. 58. 8. Le Grebe Duc-laart, Bus. Ois. viii. p. 240. 8. BLACK-BREAST-ED GR.

SIZE of a small Fowl. Bill one inch long, black, with a pale tip: irides white: the head and upper parts are dull brown: between the bill and eye is a white spot: the under parts are white, except a large spot of black on the breast; and the belly, sides, and thighs, spotted with grey: the wing coverts are pale rusous: legs dusky.

DESCRIPTION.

This inhabits the isle of St. Thomas, and is called Duc-laart.

Рp

body,

body, reddish brown; very pale on the rump: sides of the head and fore part of the neck yellowish grey*: chin the same, but paler: breast and belly white, mottled with ash-colour and red: thighs and vent grey: legs dirty green. Male and female much alike, and both vary according to the age, as in other species.

PLACE AND MANNERS.

This species frequents the same places with the other Grebes, but is infinitely more common, sew fresh waters being without it. It makes a large nest, a foot or more in thickness, in the water, composed of grass and other water plants, and lays five or six dirty yellowish white eggs; the nest is so placed in the water that it is constantly kept wet, which seems essential to the hatching of the young brood both of this and other species of the genus. The food is sish, water insects, and plants. It is an admirable diver, and seems to make way under the water at a very great rate, arising at an inconceivable distance from the place it plunges in at; for the most part, considerably beyond the length of gunshot. We believe this bird to be pretty frequent on the old continent; it is likewise found common at Hudson's Bay in America, where it is called Dishishet seekeep. In England called by the various names of Didapper, Dipper, Loon, and Dobchick.

10. Var. A: Le Castagneux des Philippines, Buf. Oif. vi. p. 246 .- Pl. Enl. 945.

DESCRIPTION.

HIS is rather larger than the little Grebe, and differs from it in a few particulars. The upper parts are brown, as in that

DESCRIPTION.

ьŦ

and turns up towards the end, where it finishes in a sharp point; the nostrils narrow and pervious: irides hazel: the top of the head, taking in the eyes, is black, passing some way down the neck, and ending in a point: above and beneath the eye a spot of white: the remainder of the head and neck, and all the under parts, are white: the back, major part of the scapulars, outer part of the wing, and lesser quills and tail, are of the same colour; but the inner scapulars, and all down the middle of the wing coverts, and outer webs and ends of the greater quills, are black: the legs very long, and of a pale blue; and the thighs naked for a great part of their length: the toes are webbed, the webs deeply indented; the hind toe small, and placed too high up to be of use.

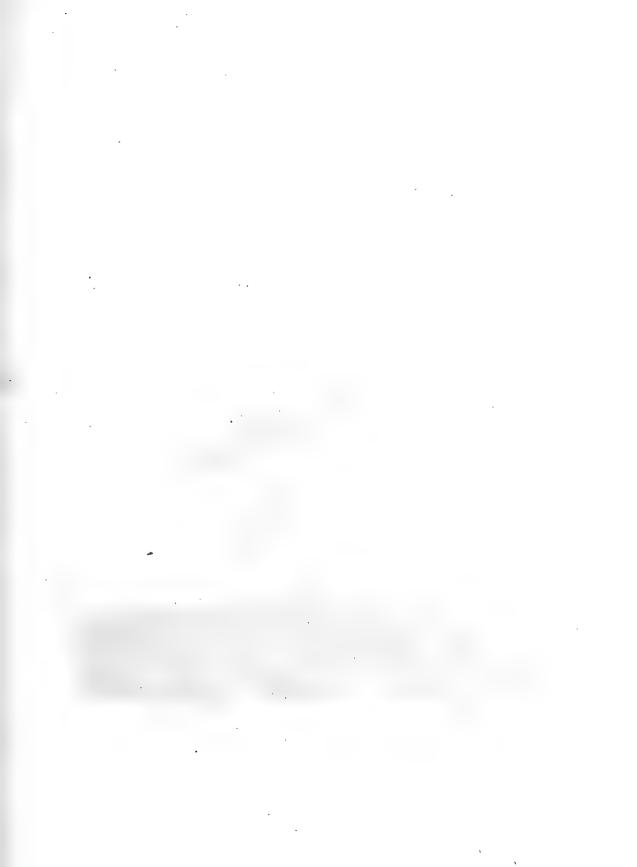

The male and female much alike.

PLACE AND MANNERS. This species is frequent, in the winter, on the sea-shores of this kingdom: in Gloucestersbire, at the Severn's mouth, the eastern coasts of Suffolk and Norfolk, and sometimes on the lakes of Shrop-shire*. Also common, at the same season, on the shores of Kent †. In the breeding season are found in the sens in vast numbers; near Fossdike Wash in Lincolnshire, in the sens of Cambridgeshire and Suffolk, and other similar places. They lay two eggs, the size of those of a Pigeon, an inch and three quarters in length, of a cinereous grey, whimsically marked with deep brownish black patches, of irregular sizes and shapes, besides some under markings of a dusky hue. They are said to feed on worms and insects; which they scoop out of the soft mud with their bills, the

American Svoset.

traces of which may be observed in the places where they frequent. Often feen to wade, as far as their legs will let them, into the water, and will also occasionally swim, but always close to the edge of the shore.

It is also seen in various parts of the continent of Europe. Found in Russia, Denmark, and Sweden*, but not in plenty; also met with in Sibiria, but more frequent about the salt lakes of the Tartarian Desart, and about the Caspian Sea+. Found on the coasts of Picardy in France, in April and November; also at Orleans, but very rare. In breeding time in such plenty on the coasts of Bas Poistou, that the peasants take their eggs by thousands in order to feast on them ‡. We have not been able to trace these birds further south in Europe than Italy, where they have been long noticed as inhabitants.

GENUS LXXXI. COURIER.

Nº 1. Italian C.

ILL short, strait.

Legs long: thighs short: feet palmated, and furnished with a back toe.

ITALIAN C.

Le Coureur, Bris. Orn. vi. p. 542. Trochilus, or Corrira, Raii Syn. 118. 3.—Will. Orn. p. 321. pl. 60.

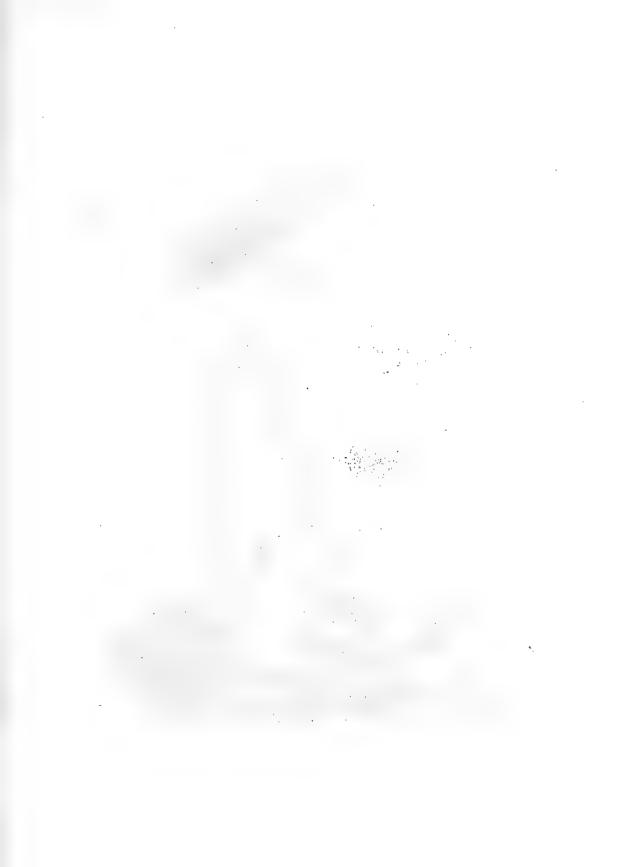

Description.

THIS bird is faid to be lefs than the Avoset, and the legs not fo long in proportion. The bill shorter, strait, yellow, with a black tip: irides of two colours, first white, surrounded with chesnut: the head, and all the upper parts of the body and wings, are ferruginous: the under parts white: the two middle tail feathers are white, tipped with black: the others supposed to be black: toes webbed, as in the Avoset.

PLACE.

This bird is faid to inhabit *Italy*, and to run very fast; whence the name given to it. *Aldrovandus* * is the only one who has feen the bird; and it is from him alone that the succeeding authors have all had the description and figure.

* Av. tom iii. p. 288. fig. in p. 289.

Red Flamingo.

GENUS LXXXII. FLAMINGO.

Nº 1. Red Flamingo.

THE bill in this genus is thick, large, bending in the middle, forming a sharp angle; the higher part of the upper mandible carinated; the lower compressed; the edges of the upper mandible sharply denticulated; of the lower, transversely sulcated.

Nostrils covered above with a thin plate, pervious, linearly longitudinal.

Tongue cartilaginous, and pointed at the end; the middle muscular; base glandular; on the upper part aculeated.

Neck very long.

Legs and thighs of a great length.

Feet webbed; the webs extend as far as the claws, but are deeply femilunated.

Back toe very fmall.

THIS fingular bird is scarce so big as a Goose; but has the neck and legs in a greater disproportion to the body than any Q Q 2

DESCRIPTION.

+ RED FL.

PL. XCIII.

other bird: the length, from the end of the bill to that of the tail, is four feet two or three inches; but to the end of the claws fometimes measures more than fix feet. The bill is four inches and a quarter long, and of a construction different from that of any other bird; the upper mandible very thin and flat, and fomewhat moveable; the under thick; both of them bending downwards from the middle: the nostrils are linear, and placed in a blackish membrane: the end of the bill, as far as the bend, is black, from thence to the base reddish yellow; round the base, quite to the eye, covered with a flesh-coloured cere: the neck is slender, and of a great length: the tongue large, fleshy, filling the cavity of the bill; furnished with twelve or more hooked papillæ on each side, turning backwards; the tip a sharp cartilaginous substance. The bird, when in full plumage, is wholly of a most beautiful deep scarlet*, except the quills, which are black: from the base of the thigh to the claws measures thirty-two inches, of which the feathered part takes up no more than three inches; the bare part above the knee thirteen inches; and from thence to the claws fixteen: the colour of the bare parts is red; and the toes are furnished with a web, as in the Duck genus, but is deeply indented.

Young.

These birds do not gain their full plumage till the third year. In the first they are of a greyish white for the most part; the second of a clearer white, tinged with red, or rather rose-colour, but the wings and scapulars are red; in the third year a general glowing scarlet manifests itself throughout: the bill and legs also keep pace with the gradation of colour in the plumage,

[·] Those of Africa said to be deepest coloured.

these parts changing to their colours by degrees, as the bird approaches to an adult state.

Flamingoes prefer a warm climate: in the old continent not often met with beyond 40 degrees north or fouth. Every where feen on the African coast and adjacent isles, quite to the Cape of Good Hope*; and now and then on the coasts of Spain +, Italy, and those of France lying in the Mediterranean Sea; being at times met with at Marseilles, and for some way up the Rhone. In some feasons frequent Aleppo I and parts adjacent. Seen also on the Persian side of the Caspian Sea, and from thence along the western coast, as far as the Wolga; though this at uncertain times, and chiefly in confiderable flocks, coming from the north-east, mostly in October and November; but so soon as the wind changes they totally disappear §. They breed in the Cape Verd isles, particularly in that of Sal ||. The neft is of a fingular construction, made of mud, in shape of an billock, with a cavity at top; in this the female lays generally two white eggs **, of the fize of those of a Goofe, but more elongated. The hillock is of fuch an height as to admit of the bird's fitting on it conveniently, or rather standing, as the legs are placed one on each side at full length ††.

^{**} They never lay more than three, and feldom fewer.-Phil. Trans.

^{††} Sometimes will lay the eggs on a projecting part of a low rock, if it be placed sufficiently convenient so as to admit of the legs being placed one on each side.—Linn.

Flamingoes for the most part keep together in flocks; and now and then are feen in great numbers together, except in breedingtime. Dampier mentions having, with two more in company, killed fourteen at once; but this was effected by fecreting themfelves, for they are very shy birds, and will by no means suffer any one to approach openly near enough to shoot them *. Kolben observes that they are very numerous at the Cape, keeping in the day on the borders of the lakes and rivers, and lodging themfelves of nights in the long grass on the hills. They are likewife common to various places in the warmer parts of America. frequenting the fame latitudes as in other quarters of the world; being met with in Peru and Chili, Cayenne +, and the coast of Brafil, as well as the various islands of the West Indies. Sloane found them in Jamaica; but particularly at the Bahama islands, and that of Cuba, where they breed. When feen at a diftance they appear as a regiment of foldiers, being ranged alongfide one another on the borders of the rivers fearching for food, which chiefly confifts of small fish t, or the eggs of them, and of water-insects, which they search after by plunging in the bill and part of the head, from time to time trampling with their feet to muddy the water, that their prey may be raifed from the bottom. In feeding are faid to twift the neck in fuch a manner that the upper part of the bill is applied to the ground §: during this one of them is faid to ftand centinel, and the moment

he founds the alarm the whole flock take wing. This bird, when at rest, stands on one leg, the other being drawn up close to the body, with the head placed under the wing on that side of the body it stands on.

The flesh of these birds is esteemed pretty good meat, and the young thought by some equal to that of the Partridge*; but the greatest dainty is the tongue, which was esteemed by the ancients an exquisite morsel †. Are sometimes caught young, and brought up tame; but are ever impatient of cold: and in this state will seldom live a great while, gradually losing their colour, slesh, and appetite, and dying for want of that food which in a state of nature at large they were abundantly supplied with.

^{*} Commonly fat, and accounted delicate.—Davies Hift. Barbad. p. 88.—The inhabitants of Provence always throw away the flesh, as it tasses fishy; and only make use of the feathers as ornaments to other birds at particular entertainments.—Dillon Trav. p. 374. extr.

Description.

PIGGER than a Swan: length from three feet fix inches to four feet: the general extent is ten feet from wing to wing; but many of our voyagers mention them as greatly exceeding these

these dimensions*: weight from twelve to twenty-eight pounds. The bill dirty yellow: crown of the head pale cinereous brown: the rest of the body for the most part white, crossed with blackish lines on the back and wings, and with spots in the same direction towards the rump: the greater quills are black: the tail dusky lead-colour, and rounded in shape: legs sless-colour.

The young birds are faid to be brown; as they advance have more or less a mixture of white; but do not become of the colour of the above-described till mature age.

Albatrosses are very frequent in many parts without the tropics, both to the northward as well as south; not being by any means confined to the last, as has been by some imagined †. Indeed they are in great plenty in the neighbourhood of the Cape of Good Hope, as all voyagers can testify; and not only these but other forts also, and from thence in every temperate southern latitude ‡, as far towards the pole as has yet been exploded.

These birds are also often seen in vast slocks in Kamtschatka, and adjacent islands, about the end of June, where they are called Great Gulls; but it is chiefly in the bay of Penschinensi, the whole inner sea of Kamtschatka, the Kurile isles, and that of Bering; for on the eastern coasts of the first they are scarce, a single straggler only appearing now and then. Their chief motive for

See Voy. p. 5.

⁺ Buf. Oif. ix. p. 339.

[†] Seldom below 30 degrees: never in the torrid zone. Forst. Voy. i. p. 482. Vol. III. Rr frequenting

frequenting these places seems to be plenty of food; and their arrival is a fure prefage of shoals of fish following. At their first coming are very lean, but foon grow immensely fat. Are very voracious birds, and will often swallow a Salmon of four or five pounds weight; but as they cannot take the whole of it into their stomach at once, part of the tail end will often remain out of the mouth; and the natives, finding the bird in this fituation, make no difficult matter of knocking it on the head on the spot. Before the middle of August they migrate elsewhere. They are often taken by means of a hook baited with a filb*; but it is not for the fake of their flesh that they are valued, it being hard and unfavoury t, but on account of the intestines, a particular part of which they blow up as a bladder, to ferve as floats to buoy up their nets in fishing. Of the bones they make tobacco-pipes, needle-cases, and other useful-things 1. When caught they defend themselves stoutly with the bill. Their cry is harsh and disagreeable, not unlike the braying of an A/s &. The breeding places of the Albatross, if at all in the northern hemisphere, have not yet been pointed out; but we are certain of their multiplying in the fouthern, viz. Patagonia | and Falkland Islands **: to

6

[•] Forster mentions nine being caught with a line and hook baited with a bit of sheep's skin -Voy. i. p. 87.-Cook's Voy. i. p. 84.

[†] Yet they were eaten by our voyagers.—As foon as caught they were skinned, and foaked in falt-water till next morning; then parboiled, and the liquor being thrown away, stewed with fresh-water till tender; and being served up with savoury sauce, they were much commended.—Hawkes. Voy. iii. p. 66.

Ara. Zool. ** Clayton.

this last place they come about the end of September or beginning of October, among other birds, in great abundance *. The nests are made on the ground with earth †, are round in shape, a foot in height, indented at top. The egg larger than that of a Goofe, four inches and a half long, white, marked with dull spots at the bigger end; and is thought to be good food, the white never growing hard with boiling. While the female is fitting the male is conftantly on the wing, and supplies her with food: during this time are so tame as to suffer themselves to be shoved off the nest while their eggs are taken from them; but their chief destruction arises from the Hawk 1, which, the moment the female gets off the nest, darts thereon, and slies away with the egg. The Albatross itself likewise has its enemy, being greatly persecuted while on the wing by the dark grey Gull, called Skua. This bird attacks it on all fides, but particularly endeavours to get beneath, which is only prevented by the first settling on the water | ; and indeed they do not frequently fly at a great diftance from the furface, except obliged fo to do by high winds &. or other causes. As soon as the young are able to remove from the nest, the Penguins take possession, and hatch their young in turn. It is probable that they pass from one part of the globe to another according to the feafon; being now and then met with,

^{*} A part of New Zealand is called Albatross Point, from this circumstance.— Parkins. Voy. p. 113.

by different voyagers, at various times, in intermediate places*. The food is supposed to be chiefly small marine animals, especially of the Mollusca or Blubber class †, as well as Flying Fish ‡.

CHOCOLATE A.

Deep brown, or chocolate Albatross, Cook's Voy. ii. p. 116. 150 ||.

Lev. Mus.

DESCRIPTION.

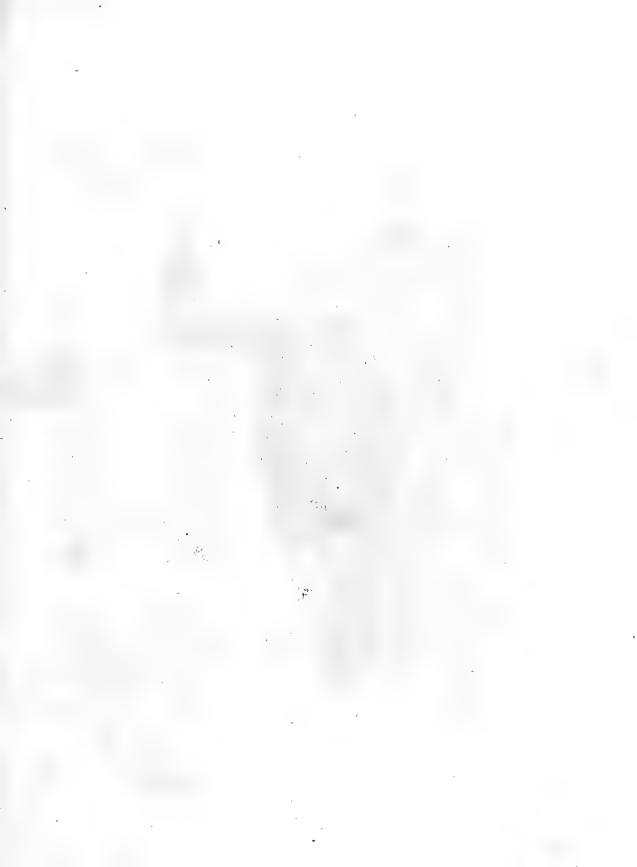

SIZE larger than the Sooty Albatrofs. The bill in this bird of a yellowish white: irides brown: fore part of the head, round the eye, chin, and throat, white: the plumage in general of a fine deep chocolate-colour; the neck and under parts palest: the inner ridge of the wing, and under wing coverts, white; and the belly inclines much to white: the tail is short, rounded in shape; that and the wings equal in length: the legs blueish white: claws white.

PLACE.

This bird varies in having more or less white about the head, and in a greater or less degree of purity. Seen in the South Seas, in lat. 37, the end of December.

- * Seen between fix and seven hundred leagues from land, in the middle of the southern ocean.—Forst. Obs. p. 211.—Met with at the Sandwich Islands.—Ellis Narr. ii. p. 149.—Also in lat. 26. 31. N. on the 4th of April.—Id. p. 193.—Off Japan and Jesso, in Ostober 1771.—Cook's last Voy. vol. iii. p. 391.—Lat. 33. S. May 5.—Osbeck Voy. i. p. 109.
 - + Forft. Voy. i. p. 118.
 - 1 Anan. Acad. v. p. 75.—Ara. Zool. Nº 507.
- As few of the voyagers have thought worth while to describe the birds to which they have given names, we cannot always be clear of the species meant: are therefore not quite certain it was the one here described.—Chocolate Albatross also mentioned by Forster; but were not observed by him, except among the ice.—Voy. i. p. 258.—Perhaps the Albatross with a white beak.—Park. Voy. p. 83. 84?

Bro

Wellow- nosed Albatrofs.

Br. Muf.

Long, hooked at the end, but not very flout; the colour of it is black, except the upper ridge, which is yellow the whole length, quite to the tip, where it is hooked; the base of the under mandible is also yellow: irides brown: the head is grey: between the bill and eyes is an obscure black spot; just over the eye a dusky one: the hind part of the neck dusky, the lower part white: back, scapulars, and wings, dusky blue black: rump, and under part of the body, white: the tail dusky: the legs are pale yellowish white; the fore part of them, and the webs, dusky.

This species is met with in the southern hemisphere, from 30 to 60 degrees, all round the pole*. The specimen from whence the above description was drawn up, was taken off the Cape of Good Hope. Inhabits the South Seas without the tropics. Fly about five or six feet above the surface of the water.

the body, wings, and tail, is black; the rest white; and there is a large oval spot of the last, occupying most of the space between the bill and eye: the second quills are tipped with white, forming an oblong stripe on the wings; which are so small as to be useless for slight, being little more than four inches in length to the first joint: legs black.

In Mr. Tunstall's Museum is one of these with only two or three furrows on the bill, and the oval space between the bill and eye speckled black and white. This is probably a young bird.

PLACE AND MANNERS.

This bird is fometimes feen on the isle of St. Kilda, appearing there the beginning of May, and retiring in June. It lays one large egg, close to the fea mark, fix inches long, white, irregularly marked with purplish lines, and blotched at the larger end with black or ferruginous spots; and it is faid, that if the egg be taken away the bird will not lay a fecond. It hatches late, as the young in August are only covered with grey down. It is feldom to be met with beyond foundings. Sometimes frequents the coasts of Norway, the Ferroe Isles, Iceland, Greenland, and Newfoundland*. Feeds much on the lump-fish, father-lasher, and other fish of that size. The young birds eat rose-root t, and other plants. The old ones are very rarely feen on shore, though the young are not unfrequently met with: is a very fly bird; walks ill, but dives well, and is taken in the manner used for the Razorbill and Puffin. The skin between the jaws is blown into a bladder, and used for the darts of the Greenlanders, as is also that of some other birds I. The skin of the body supposed to be used by the Eskimaux Indians for garments ||.

PL. XCV. Fig. 1.

DESCRIPTION.

Lew. Mus.

THIS is somewhat bigger than the common Puffin: length nineteen inches. Bill an inch and three quarters in length, the same in depth at the base, and crossed with three surrows: the colours much as in the common Puffin: the forehead, sides of the head, and chin, are white: irides yellowish brown: over each eye arises a tust of feathers four inches or more in length, which falls elegantly on each side of the neck, reaching almost to the back; these are white as far as they are attached to the head, but afterwards of a fine buff yellow: the rest of the plumage is black, palest on the under parts, and inclining to ash-colour: the shafts of the quills are white: tail very short, consisting of sixteen feathers: legs of a brownish orange: claws black.

The female scarcely differs, except in being less *; the bill crossed only with two furrows, instead of three; and the tust smaller.

This species is found at Kamtschatka, and the neighbouring islands. Our last voyagers first met with it a little to the south of Cape Hermogenes, and after that daily, sometimes in large slocks †. Pallas ‡ remarks, that the Kamtschatkan girls imitate the tusts of these birds, which nature has supplied them with, by placing a similar strip of the white skin of the Glutton behind each ear, hanging down behind by way of ornament; and is a well-received present from a lover to his mistress. The bills both

of this and the common Puffin were formerly held by the natives as a charm, and worn by the priests as amulets; indeed at the present these have been seen sixed round their head dresses, but supposed now to be only esteemed as mere ornaments: the skins are however made use of for cloathing, being sewed together. It is called in Kamtschatka, Muechagatka; and in Oschotka, Igilma*. The manners of this coincide with the last, and like that it burrows under ground, lining the nest with seathers and sea-plants. Lays one white egg, the end of May or beginning of June, which alone is thought sit to be eaten, the slesh of the bird itself being insipid and hard. It feeds on crabs, shrimps, and shell-sish, which last it forces from the rocks with its strong bill †.

Br. Muf. Lev. Muf.

DESCRIPTION.

SIZE of a Teal: length twelve inches: breadth twenty-one: weight twelve ounces. The bill is an inch and a quarter long, and of a fingular shape, much compressed on the sides, and near an inch and a half deep at the base; from whence both mandibles tend to a point, which is a little curved; across the upper are four oblique surrows; on the under three: half of the

* Hist. Kamtsch. p. 183. † Arct. Zool.

bill next the point is red; that next the base blue grey; and at the base is a fort of rising cere, full of minute holes: the nostrils are a long and narrow slit on each side, near the edge of the upper mandible, and parallel to it: the irides are grey: the edges of the eye-lids crimson; on the upper, a callous protuberance, triangular in shape; on the under, an oblong one of the same texture: the top of the head, hind part of the neck, and all the upper parts of the plumage, are black, passing round the throat in a collar: the sides of the head, chin, and all the parts beneath, are of the purest white: the legs are orange: in some birds there is a great portion of a dusky mixture on the cheeks, and a patch of the same on each side of the under jaw.

Male and female much alike.

They vary exceedingly, in regard to the bill, according to their age: in the first year it is small, weak, destitute of any surrow, and of a dusky colour: in the second, larger, stronger, and lighter coloured, with a faint vestige of a surrow at the base; but those of more advanced years are of vivid colours, and great strength: hence these birds are supposed not to be perfect, or at least not to breed, till the third year, especially as not a single one has ever been observed at *Priestholm* which had not the bill of an uniform growth *.

This species frequents several parts of the coasts of England; a few about the rocks at Dover, and the neighbourhood; great numbers about the Needles, in the Isle of Wight, Beachy Head, and other parts; but no where in such plenty as at Priestholm Isle, where they are seen in slocks innumerable. They come to that

PLACE AND MANNERS.

^{*} See Tour in Wales, p. 252; and figures of the different growths of the bill in pl. 20.—Compare the Alca Deleta of Brunnich and Muller—Pall. Spic. ii. p. 22.

place from the 5th to the 10th of April; but quit the place again, and return, twice or thrice before they fettle to burrow, which they do the first week in May, when many of them dislodge the Rabbits from their holes, by which they fave themselves the trouble of forming one of their own: in the last case, they are fo intent on what they are about, as to fuffer themselves to be taken by the hand. It has been observed that this task falls chiefly to the share of the males, and that these last also assist in incubation: this has been proved on diffection. The female lays one white egg: the young are hatched the beginning of July: and about the eleventh of August they all go off, to a fingle bird, and fo completely as to defert the young ones that are late hatched; leaving them a prey to the Peregrine Falcon, who watches at the mouth of the holes for them as they, through hunger, are compelled to come out. Notwithstanding the neglect of the young at this time, no bird is more attentive to them in general, as they will fuffer themselves to be taken by the hand, and use every means of defence in their power to fave them; and, if laid hold of by the wings, will give themselves most cruel bites on any part of the body they can reach, as if actuated by despair; and when released, instead of flying away, will often hurry again into the burrow to their young*.

The food of these birds is sprats, the smaller kind of crabs, and sea-weeds: they are excessively rank, yet the young are preserved with spices, and pickled, and by some people much admired +.

^{*} Ara. Zool.

[†] Are potted at St. Kilda and elsewhere, and sent to London as rarities. The bones are taken out, and the slesh wrapped in the skin; are eaten with vinegar, and taste like baked Herring.

They

They are also common in Ireland; on the island Sherries, three leagues N. N. W. of Holyhead; and in the S. Stack, near Holyhead, they breed in plenty*. Inhabit Iceland and Greenland; and breed in the extreme part of the islands, especially on the west part of Disco, and the island Orpiksauk. Found in the Ferroe isles, and there called Lunda. In the Farn Isles called Coulter-neb, from the shape of the bill: it goes also by various other names; such as Guldenhead, Bottle-nose, and Helegug, in Wales; at Scarborough Mullet; and Cornwall, Pope +.

In America are faid to frequent Carolina in winter; and have been met with in Sandwich Sound by our late voyagers: the natives ornament the fore parts and collar of their Seal-skin jackets with the beaks of them; and those of Aoonalashka wear gowns of their skins, along with those of other birds.

On the coast of Kamtschatka and the Kurilschi islands they are common, even on the Penschinski Bay, almost as far as Ochotka: the nations of the two first wear the bills about their necks fastened to straps; and, according to the superstition of these people, their Shaman or Priest must put them on with a proper ceremony, in order to procure good fortune ‡.

ENGTH fixteen inches. The bill two inches long, much of the same colour with the last, but not so deep at the base: crown of the head, as far as the nape, ash-colour: sides of

Br. Mus. Lev. Mus.

ENGTH eighteen inches: breadth twenty-feven. Bill two inches long, black, curved at the point; the feathers coming greatly forwards at the base, and croffed with four transverse grooves, one of which is white, forming an oblique band on both mandibles: inside of the mouth yellow: from the base of the forehead to the eye a narrow line of white: the rest of the head, chin, throat, back part of the neck, back, wings, and tail, black: under parts from the breast white: the greater wing coverts tipped with white, forming a band on the wings: legs black.

These birds, like the Auk, recognise their old breeding-places before they settle thereon to breed: appear first the beginning of February, but do not settle on their breeding-places with an intent to lay till the beginning of May, when they are met with on most of the high craggy coasts of England; where our merciless shooters go to try the use of the gun, too frequently leaving many hundreds of these and the Guillemots, after being maimed, to die by slow degrees at the foot of the rocks; for they are so stupid as to suffer themselves to be shot at one after another. They are called by some, Parrot-billed Willocks; and lay one egg on the bare rock, which they so fix by cement* to the surface,

DESCRIPTION.

PLACE AND MANNERS.

^{*} See Art. Zool. p. 510.

that it rests secure from rolling off, yet if disturbed by human hand can never be replaced with certainty: if this be taken away it will lay another, and even a third, should the second be also taken. The colour of the egg is dusky white, marked with many irregular blackish spots.

These eggs the natives are fond of, and run the greatest risk in procuring them, being lowered from above by ropes. Sometimes two persons, having a rope tied to each of their middles, the one takes fast hold, while the other lowers himself as convenience serves; but the weight of the lower one sometimes exceeding the uncertain hold of his companion, they both fall, and perish together.

We find these birds in the north of Europe, also in Iceland, Greenland, and on the coast of Labrador. In Europe they extend along the White Sea into the Artic Asiatic shores, and from thence to Kamtschatka and the gulph of Ochotka. Is the only one which reaches the inland Baltic; being found there on the Carls-Ozar Isles, near Gothland, and the isle of Bondon off Angermania*.
